[1] Dengue: 2 cases at Charleston, S C.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended September 11, 1926, compared with those for a like period ended September 12, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925, and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, August 8 to September 11, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

BOLIVIA

Influenza—July, 1926.—Influenza was reported extensively diffused in Bolivia during the month of July, 1926. At La Paz schools were closed from July 15 to 25. Hospital records showed 19 deaths from influenza during the month.

BRAZIL

Smallpox—Rio de Janeiro—January 1–August 14, 1926—During the period January 1 to August 14, 1926, 1,908 cases of smallpox with 945 deaths were reported. Population, 1,543,212.

CANADA

Communicable diseases—Two weeks ended September 11, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the weeks ended September 4 and September 11, 1926, as follows:

WEEK ENDED SEPTEMBER 4

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				1		5		6
Influenza	9				2			11
Smallpox				5	2	11	1	19
Typhoid fever	1	7	13	18	12		4	55

WEEK ENDED SEPTEMBER 11

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever					3	6		9
Influenza	5							5
Poliomyelitis				4				4
Smallpox				7	4		2	13
Typhoid fever	2	10	38	18	5		4	77

CEYLON

Health conditions, year 1925.—Disease prevalence was reported in the Island of Ceylon during the year 1925 as follows: *Smallpox*—28 cases, three deaths, as compared with the preceding year with 49 cases, nine deaths; and with 1923 with 280 cases, 39 deaths. The 22 cases reported at Colombo during the year were all from vesssels calling at the port. In 1924 the number of cases from vessels was four. The absence of spread from the imported cases in 1925 was

attributed to efficient preventive measures on the part of port authorities. *Cholera*—Cases, 305, deaths, 186. A number of outbreaks were attributed to cholera carriers Comparison with previous years shows for 1924 only 17 cases with 14 deaths, and in 1923 no reported cases.

CHOSEN

Cholera—Shingishu—A report received from Seoul, Chosen, shows cholera present at Shingishu and in vicinity, September 13, 1926.

ECUADOR

Plague—Summary, January-June, 1926.—Information has been received under date of July 31, 1926, showing the prevalence of plague in Ecuador during the period January to June, inclusive, 1926, as follows:

Province	Cases	Deaths	Number of localities
Chimborazo	9	2	At four localities
Guayas	74	29	At Guayaquil
Leon	43	19	At two localities
Loja	176	75	In two cantons
Tungurahua	83	29	At Ambato, Huachi, and Picayhua

Rats taken—Found infected—In the Province of Chimborazo, 766 rats were reported taken at four localities, in the Province of Guayas, at Guayaquil, 124,453 rats, of which 697 were found infected; in the Province of Tungurahua, 1,542 rats were taken at three localities.

Plague—Guayaquil—August, 1926—During the month of August, 1926, seven cases of plague with one death were reported at Guayaquil, Ecuador.

Plague-infected rats.—During the period under report 21,155 rats were reported taken and 37 rats found infected.

GERMANY

Poliomyelitis (infantile paralysis)—Magdeburg—Nordhausen.—Under date of September 7, 1926, the occurrence of poliomyelitis (infantile paralysis) was reported in central Germany. At Nordhausen 17 cases were reported and at Magdeburg the disease was stated to be present.

GREAT BRITAIN

Further relative to plague—Liverpool[1]—Information received under date of September 8, 1926, relative to plague reported present at Liverpool with several cases and one death, September 6, 1926,

[1] Public Health Reports, Sept 17, 1926, p 2056

shows that the occurrence was in a father and son, a boy of 10 years, who died of the disease, and that the father was employed at the Liverpool South End Docks.

LATVIA

Communicable diseases—July, 1926.—During the month of July, 1926, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	2	Mumps	8
Diphtheria	31	Paratyphoid fever	6
Dysentery	20	Puerperal fever	2
Erysipelas	30	Scarlet fever	176
Leprosy	3	Trachoma	20
Malaria	1	Typhoid fever	61
Measles	52	Whooping cough	77

Population, estimated, 1,850,000

MADAGASCAR

Plague—June 16 to 30, 1926.—During the period June 16 to 30, 1926, 43 cases of plague with 31 deaths were reported in the island of Madagascar. The occurrence was distributed in five Provinces as follows: Antisirabi, cases, 4; Itasy, cases, 17; Majunga, cases, 10; Mananjary, 1 case; Tananarive, cases, 10. The urban occurrence was: Tamatave (port), 1 case; Tananarive (interior), 1 case. According to type the distribution was: Bubonic, 10 cases; pneumonic, 30; septicemic, 3.

MALTA

Communicable diseases—July, 1926.—Communicable diseases were reported in the island of Malta during the month of July, 1926, as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	3	Pneumonia	5
Chicken pox	9	Scarlet fever	2
Diphtheria	7	Trachoma	46
Erysipelas	6	Tuberculosis	16
Malta fever	91	Typhoid fever	42
Measles	68	Whooping cough	3

PANAMA CANAL

Communicable diseases—July, 1926.—During the month of July, 1926, communicable diseases were reported in the Canal Zone, and at Colon and Panama, as follows:

Disease	Canal Zone		Colon		Panama		Infected in other localities		Total	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
Chicken pox					1				1	
Diphtheria	2				12				14	
Dysentery		1			1				1	1
Hookworm				1	33				33	1
Leprosy			1		1				2	
Malaria	220		15		6	1	41		282	1
Measles	1		1		10				12	
Meningitis				1						1
Pneumonia [1]				6		11				17
Poliomyelitis			1						1	
Tuberculosis [1]		1		9		15		2		27
Whooping cough			1	1	1				2	1

[1] Only deaths reported

PERU

Mortality from gastroenteritis—Lima—May and June, 1926.—During the months of May and June, 1926, 38 and 32 deaths, respectively, from gastroenteritis, were reported at Lima, Peru

Influenza—During the same months, 10 and 7 deaths, respectively, from influenza were reported at Lima The total number of deaths reported for the month of May was 365, for the month of June, 349. Population, estimated, 200,000.

SAMOA

Epidemic influenza—Apia—Under date of August 21, 1926, epidemic influenza in a mild but highly infectious form was reported present at Apia, Samoa, and vicinity. The infected area was stated to extend along the coast The estimated number of cases was 200. No mortality was reported.

Bacillary dysentery—Measles.—During the week ended July 31, 1926, two cases of bacillary dysentery were reported in the Government hospital; during the week ended August 21, 1926, 13 cases of measles were reported at a village in vicinity of Apia, with no other infected area noted

VENEZUELA

Proposed water-supply system—Maracaibo.—A report of the preliminary work on the aqueduct system at Maracaibo to July 15, 1926, has been received. It is estimated that the supply of water furnished will give each inhabitant 172 liters of water daily on a basis of 100,000 population. The source of the supply is the Rio Palmar, which is estimated to have a flow of 3,860 liters per second and to be sufficient to supply water for 19 cities of the size of Maracaibo. The water is stated to be of fine quality.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

The reports contained in the following tables must not be considered as complete or final as regards either the lists of countries included or the figures for the particular countries for which reports are given.

Reports Received During Week Ended October 1, 1926 [1]

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C. C. PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 OCTOBER 8, 1926 NO. 41

REPORT OF AN EPIDEMIC OF GLANDULAR FEVER (INFECTIOUS MONONUCLEOSIS)

By R R SPENCER, Surgeon, United States Public Health Service

On July 27, 1926, Dr C T Smith, of Rocky Mount, N C., reported the occurrence of about 30 cases of a disease characterized by high continuous fever, enlargement of the spleen and lymph glands, and a macular rash appearing over the chest, abdomen, and extremities about the third or fourth day of fever Widal tests were invariably negative and the condition did not respond to quinine administration.

The writer arrived in Rocky Mount, a city of about 16,000 population, on July 28, 1926, and was able to see many of these cases, the majority of which, however, were then in the convalescent stage. The outbreak had begun, as far as could be ascertained, about the first week in July, the largest number of cases occurring from July 10 to 20 It is probable that sporadic cases had occurred before. One physician reported that his 11-year old daughter had a similar infection with enlarged lymph glands a year previously.

SYMPTOMATOLOGY

The typical cases were characterized by a few days of general malaise, followed by one or more chills and fever, a general aching all over the body especially severe in the eye muscles and occipital region Nausea and vomiting and a slight sore throat occurred in about half the cases seen. The fever was usually high at first and gradually tapered off to normal, with an average duration of 7 to 10 days. In one typical case (No. 8) the temperature on the 29th day was 101° F in the afternoon Enlarged tender lymph glands developed in 14 of the 26 cases tabulated below. In some instances the enlarged glands did not develop or were not recognized until late in the illness. Suppuration of the glands did not occur An unusual feature of the condition was the appearance of a faint but definite rose-colored macular rash over the chest, abdomen, and flexor surfaces of the arms in 13 of the 26 cases. In one case (No. 21) the rash was definitely maculo-papular and covered the entire body except the face This case did not show enlarged glands and the patient's blood on the 15th day after onset did not agglutinate *B. tularense* or *B. proteus* X_{19} As a rule, convalescence was prolonged, the patients remaining weak for days. There were no fatalities.

AGE AND SEX DISTRIBUTION

Although the cases tabulated in Table 1 show a preponderance of males (18 males, 8 females), the sexes were about equally represented in the total number of cases recorded. In the cases shown in Table 1 age distribution varied from 3 years to 58 years. Thirty-two cases not tabulated, however, were all in young adults from 15 to 28 years of age.

ANIMAL INOCULATION

Guinea pigs were injected with citrated blood from cases No. 1 and No. 19 (Table 1) taken on the fourteenth and third day of fever, respectively. These animals showed no elevation of temperature and remained normal for 18 days.

EPIDEMIOLOGICAL DATA

Since the etiology and mode of spread of this condition were unknown, an investigation was made along the following lines:

City water supply.—An inspection of the city filtration plant showed that the daily consumption at this time of year is about 2,000,000 gallons. This amount does not tax the capacity of the plant. The water taken from the Tar River is first treated with 500 pounds of alum and 25 pounds of soda per day and permitted to settle in a baffled reservoir of 250,000 gallons capacity. It is then passed through six rapid sand pressure filters. These filters are washed every twelve hours by reverse flow. The clear water is then treated with 3½ pounds of chlorine gas (Wallace and Tiernan apparatus) per million gallons. A bacteriological count is made

daily at the city health department. The records show that the water rarely has had a total count in excess of 100 organisms per c. c. and that *B. coli* has been invariably absent in 10 c. c amounts for the preceding two or three months. Under such conditions the water supply could not reasonably be held responsible for the epidemic.

In addition, two of the cases seen occurred at homes out of the city, each having its own source of water Other cases were also reported from adjacent country

Milk supply—Among 30 typical cases, 12 stated they drank no milk, 7 had milk from their own or neighbor's cows, 5 obtained milk from C's dairy, 3 from the L R. dairy, 2 from G's dairy, and 1 from M. B dairy. It is therefore safe to conclude that no one source of milk could have been responsible for the outbreak. There was no indication that other dairy products such as cheese, butter, or buttermilk were involved

Ice cream.—Practically all the ice cream sold to the public in Rocky Mount is furnished by one company. The ice-cream mixture for the local plant of that company is prepared at Wilson, N. C. The Wilson plant was inspected on August 7 The ice-cream mixture is pasteurized by means of steam coils at a temperature of 160° F. This temperature is held for 30 minutes, after which it is quickly cooled to about 35° F. It is then shipped by motor truck to Rocky Mount in milk cans which have been sterilized by a steam jet. It is then immediately frozen. Ice cream from the Wilson plant is also sold in localities where no cases have been reported. Several of the patients, upon being questioned, claimed never to have eaten ice cream.

Insects as possible vectors.—Because of the evidence of enlarged post cervical, post auricular, and suboccipital lymph glands, head lice were looked for especially. None were found.

A careful survey about homes as well as in the business district revealed no larvae of *Aedes aegypti,* although ideal breeding places for such mosquitoes were numerous. A few culicene mosquitoes were found.

Contagion.—The cases reported by the physicians were scattered and no definite relationship or contact appeared to exist between them. However, a house-to-house survey in a selected area of the residential section and another in the business district uncovered a number of cases that suggested a spread of the condition from one person to another. A history was also obtained of many mild and abortive attacks which would far exceed the actual number of cases seen and reported. In one family of four, the three children came down within a week, the mother escaping. The oldest boy, aged 20, who worked in a confectionery store, was taken first. In the same store, employ-

ing 8 people, 4 boys and 2 girls, ranging in age from 16 to 20, were stricken within two days. The two older employees escaped. In four of these cases enlarged glands in the post cervical and sub-occipital regions were still palpable and visible after the patients had returned to work.

In another firm of eight employees, four, all under 24 years, were taken sick from July 10 to 20. Another developed tender glands in the neck but did not feel ill enough to stop work.

In still other firms a history of two or more cases were obtained. Other firms employing from 5 to 20 workers remained free of the infection. There were many reports of indefinite illness with fever and headache or slight sore throat for one or two days among those associated with cases. Such cases as these, it is believed, were responsible for the rapid spread of the disease and for those cases where direct contact was obscure.

The residential area surveyed contained 31 homes and a total of 173 people. Four cases from this area had already been reported by physicians The survey revealed a total of 15 cases, or an attack rate of 8 6 per cent

In the business district, among 23 firms visited, having a total personnel of 272, there were 33 cases (attack rate of 12 1 per cent)

Sixteen of these patients, all of which were seen shortly after recovery, either had enlarged palpable cervical glands at the time or distinctly recalled their presence during the illness. Others had intense soreness in the neck, especially on movement, but did not remember any definite enlargement of the glands

In 11 firms, with a total of 56 employees, no case histories were elicited. The 12 firms in which cases occurred are enumerated below, showing the relationship between the number of employees and the number of cases:

Nature of firm	Number of employees	Number of cases	Nature of firm	Number of employees	Number of cases
Laundry	40	1	Dry goods	8	5
Jewelry store	5	3	Do	6	2
Department store	25	2	Furniture store	9	2
Do	6	1	Do	3	1
Do	24	3	Confectionery store	8	6
Do	20	4	Dry cleaning	15	3

DISCUSSION

The possibility that the epidemic was one of dengue fever was considered But the absence of the intermediate host, the protracted fever in many cases, and the slow convalescence seems to preclude a diagnosis of this malady.

The rash at first suggested Brill's disease, but the enlarged glands, the history of so many mild and abortive cases, the nagtive animal inoculation, the negative agglutination of *B. proteus* X_{19} in nine cases, and the blood picture seemed to rule it out completely.

Tularaemia was likewise discarded on agglutination tests and in the absence of suppurative glands.

The epidemiology, symptomatology, and laboratory finding fit in best with glandular fever, first described by Pfeiffer [1] as "Drusenfeber," and by Sprunt and Evans [2] as "Infectious mononucleosis." The frequent occurrence of a rash was the most unusual feature in our cases; and Longcope [3] reported ten cases, two of which had a macular rash over the chest and abdomen resembling rose spots. Tidy and Diniels [4] state definitely that eruptions did not occur in their cases. These authors also called attention to the persistence of enlarged palpable glands in the neck several weeks after convalescence as observed in some of our cases

Other outbreaks of glandular fever have been reported from New York, New Jersey, and Wisconsin,[5] and it is believed the condition has a wider distribution than is commonly recognized.

THE REPORTING OF NOTIFIABLE DISEASES IN A TYPICAL SMALL CITY [6]

Hagerstown Morbidity Studies No. II

By Edgar Sydenstricker, Statistician, United States Public Health Service

The completeness with which cases of diseases notifiable by law are actually reported depends upon several specific conditions and is subject to the influence of more or less intangible factors The laws requiring notification are usually quite definite and frequently demand much more than is expected or even possible. For example, in some States the disease notification laws make it the duty, not only of physicians, but also of school-teachers, administrators of institutions, and citizens generally, to report promptly all cases of a long list of diseases But what actually occurs in most instances has narrowed down to the notification of only a few of these diseases by physicians who are in attendance upon cases, largely because

A Study of Illness in a General Population Group Hagerstown Morbidity Studies No I Method of Study and General Results, was published in the Public Health Reports, Vol 41, No 39, Sept 24, 1926, pp. 2069-2088.

dependable diagnoses are sought So that the practical situation seems to resolve itself into those factors which affect the following conditions:

1. The extent to which physicians are available in a given population for attendance upon cases of notifiable diseases;
2. The extent to which the physicians in this population are called in to attend these cases; and
3. The extent to which the physicians actually report the cases they see and diagnose.

In the belief that a small contribution might be made to our knowledge of these conditions, the records obtained in a series of morbidity observations upon a general (white) population group during 28 months in Hagerstown, Md , were analyzed from the points of view set forth above, and the results are given briefly in the tables and comments which follow.

The city of Hagerstown had, at the time when the morbidity study was made, a population of about 30,000 (29,878 estimated as of February 1, 1923, the mid-date of the period covered by the study). There were 45 physicians (medical graduates), of whom 37 were engaged in general practice. This gives a ratio of one physician to 666 persons, a proportion not greatly in excess of the average for cities in the United States[7] It was found that 30 of the 37 physicians in general practice were actually practicing among the families regularly observed for the incidence of illness. If all the cases of notifiable diseases estimated to have occurred in Hagerstown had been distributed among the 37 physicians engaged in general practice, the average number which each physician would have had to report upon would have been 7 or 8 new cases per month; in the season of heaviest prevalence each physician would have had possibly one new case per day. Unless it be assumed that their practice would have been materially increased along other lines, it appears safe to assume that a sufficient number of physicians were available for attendance and reporting upon the cases of notifiable diseases which occurred in the city during the period under consideration.

The record of illness was made by trained workers visiting about 1,800 families at intervals of less than two months from December 1, 1921, to April 1, 1924.[8] The population thus observed constituted about one-fourth of the total population of the city, and the selection of families was so made as to include all sections and classes. Since excellent cooperation was given by the families visited, and the field assistants became well acquainted with the individuals and their

[7] In 1921 there was one physician to 541 persons in cities and towns having a population of 5,000 or more, according to a statement in the American Medical Association Bulletin for December, 1923 (18 465)

[8] The method of this study has been described in the first report of this series.

disease histories, it is believed that a fairly accurate record was obtained of the diseases with which we are particularly concerned here.[9] All cases seen by physicians were referred to the physicians for review as to diagnosis.

TABLE 1.—*Attendance of physicians upon cases of certain notifiable diseases observed in a general population group in Hagerstown, Md., December 1, 1921–March 31, 1924*

Disease	Number of cases observed	Per cent attended by physician
Typhoid fever	19	100.0
Meningitis	1	100.0
Pneumonia (all forms)	144	97.9
Diphtheria	45	97.8
Scarlet fever	34	97.1
Influenza	261	91.1
Measles	568	64.1
Scabies and impetigo	49	61.2
Whooping cough	374	48.8
Chicken pox	232	45.2
German measles	18	38.9
Mumps	9	33.3

The number of cases of the principal notifiable diseases which were recorded as having occurred in the population under observation for the 28-month period, and the proportion attended by physicians are shown in Table 1. The number of cases of certain diseases is too small to indicate the situation even in the population observed, but it is clearly evident that two general groups of communicable diseases may be distinguished from the point of view of medical attendance in a community which was fairly well supplied with physicians. In one group are scarlet fever, typhoid fever, pneumonia, diphtheria, and influenza,[10] over 90 per cent of the cases of each of these diseases having had medical attendance. In the second group are measles, scabies and impetigo, whooping cough, chicken pox, and probably mumps, although in the last instance the number of cases was too small to warrant any conclusion.

In so far as this experience may be regarded as at all typical, it can be interpreted that nine-tenths or more of the cases of the more serious diseases upon which public attention has been focussed come under the observation of those upon whom the health department depends for its reports. On the other hand, it is also clearly shown

[9] At the same time records of illness and disease incidence were obtained from families, a record was kept by teachers in schools of all absences due to sickness. The teachers ascertained the causes of sickness so far as it was possible to do so, and their records of disease incidence were subsequently compared with the records obtained from the families observed, with the result that a very close correspondence in nearly all diseases was found, particularly for the acute infectious diseases with which we are concerned in this communication.

[10] The classification of cases under "influenza" that were not seen by physicians was based on the informant's statements. The epidemiological evidence, which will be discussed in another report, pointed very definitely to the probability that these cases were influenza as it is commonly diagnosed, as well as against the probability that many cases actually accompanied by illness were overlooked.

that a considerably smaller proportion of cases of such common diseases as measles, impetigo, whooping cough, and chicken pox ever come to the attention of the physicians, much less to the attention of the health department itself.

The question then naturally arises, What proportion of the cases actually seen by physicians are reported? Obviously, so many factors are involved that it is hardly fair to take a single example as typical. This particular experience is not without interest, however, because a health demonstration was in progress at the time when the observations were made. The local physicians were cooperating almost unanimously with this demonstration, considerable public interest was aroused, and the conditions favorable to complete reporting were unusually good.

We did not check each individual case recorded in the observed. population group and seen by a physician with the reports sent in to the health demonstration office, and therefore we are unable to give an exact statement of what actually transpired, but it can be approximated with a fair degree of accuracy for the more frequently occurring diseases by the following method: Assuming that the observed population group was a fair sample of the entire population of Hagerstown, the total number of cases of a given disease seen by physicians can be estimated for the entire population. This estimated total may then be compared with the number of cases actually reported to the local health officer as having occurred during the same period.

TABLE 2.—*Extent to which certain notifiable diseases seen by physicians were reported by them to the local health officer in Hagerstown, Md., December 1, 1921–March 31, 1924*

Diseases	Number of cases estimated from study of sample population as seen by physicians in entire city [2]	Number of cases reported to local health officer [1]	Per cent of cases seen by physicians that were reported
Pneumonia (all forms)	595	339	57.0
Diphtheria	186	165	88.7
Scarlet fever	139	142	102.0
Influenza	996	863	86.6
Measles	1,557	627	40.3
Scabies and impetigo	127	1	0.8
Whooping cough	751	229	30.5
Chicken pox	439	151	34.4

[1] As furnished by the bureau of communicable diseases, Maryland State department of health.
[2] The number of cases represented in the first figure column of Table 1 has been multiplied by the ratio of the number of persons observed to the total population to obtain these estimates.

The results of this comparison as given in Table 2 are doubtless about what those who are familiar with the situation of disease reporting would expect. Measles, whooping cough, and chicken pox are very incompletely reported. Scabies and impetigo are an

illustration of diseases notifiable under laws which little or no attempt is made to enforce. In fact, practically all of the cases of scabies and impetigo were first seen by teachers among school children and the children were sent home with the recommendation that a physician be consulted. The total number of cases actually recorded in the families under observation undoubtedly is a minimal statement; a considerable number of cases of children with "sores" were also reported by family informants. On the other hand, the response of physicians to the demand for reports of scarlet fever and diphtheria (and typhoid and smallpox may be safely included) is evidence of their desire, as well as the general desire, for the administration of control measures. The relatively high proportion of influenza cases (as well as of pneumonia) which were reported may be regarded as a reflection of the general interest in this disease which manifested itself in epidemic form in Hagerstown in the late winter and early spring of 1923.

TABLE 3.—*A comparison of the incidence rates for certain notifiable diseases in Hagerstown, Md., based on morbidity surveys with those based on reports by physicians to the local health department, December 1, 1921–March 31, 1924*

Disease	Annual rate per 1,000	
	Based on records from regular house-to-house visits to homes of one-fourth of the total population	Based on reports of physicians to the local health department
Typhoid fever	1.15	0.96
Meningitis	.06	.03
Pneumonia (all forms)	8.72	4.86
Diphtheria	2.72	2.37
Scarlet fever	2.06	2.04
Influenza	15.80	12.38
Measles	34.39	8.99
Scabies and impetigo	2.97	.01
Whooping cough	22.64	3.28
Chicken pox	14.05	2.17
German measles	1.09	.06
Mumps	.54	.34

We may now summarize this item of experience in the reporting of notifiable diseases from the point of view of the value of a rate of incidence based upon cases *as reported*. A comparison is given in Table 3 of the rate of incidence computed upon cases recorded in a continuous canvass of a considerable population with a rate based upon cases reported by physicians. There is a great variation in the diseases. For scarlet fever, typhoid fever, diphtheria, and influenza, the rate based on reported cases approximates the actual rate fairly well, and this undoubtedly would have been true of other serious but relatively rare diseases. But the rates based on the reports for the

other more common notifiable diseases do not begin to approximate the actual rates for these diseases, in spite of the existence of conditions favorable to cooperation between the practicing physicians and the local health demonstration and of the probability that the "actual rate" is a minimal statement of the incidence of the diseases in question.

SUMMARY

In the course of a 28-month study of illnesses in a general population group in Hagerstown, Md , data were collected relating to medical attendance. These records were considered from the points of view that led to the following conclusions:

1 The number of physicians engaged in general practice was sufficient to provide for medical attendance upon all cases of notifiables diseases in this community

2 Physicians were actually called in to attend 90 per cent or more of the cases of the more serious notifiable diseases which were observed including typhoid fever, the pneumonias, diphtheria, scarlet fever, and epidemic influenza, but less than 65 per cent of cases of measles, scabies and impetigo, whooping cough, and chicken pox were attended by physicians.

3 Of cases seen by physicians, apparently 85 per cent or more of the cases of diphtheria, scarlet fever, and influenza were reported; about 60 per cent of the pneumonias and 30 to 40 per cent of measles, whooping cough, and chicken pox. Practically no scabies nor impetigo was reported. Conditions were unusually favorable for complete reporting.

4 Incidence rates based on the physicians' reports approximated fairly well the rates based on regularly repeated house-to-house inquiries for scarlet fever, typhoid fever, diphtheria, epidemic influenza, and probably other serious but rarer diseases. The incidence rates based on physicians' reports for the other more common notifiable diseases, however, fell far short of their incidence as actually observed.

ACKNOWLEDGMENTS

The continuous field observations were made by the following assistants: F. Ruth Phillips, Mrs. Mary King Phillips, Louise Simmons, Mrs. Clara Bell Ledford, Clarice Buhrman, and Mrs. Alcesta Owen, under the immediate supervision of Passed Asst Surg. R B. Norment, jr., Acting Asst. Surg A. S. Gray, and, later, of Surg. C. V. Akin. I am indebted especially to Assistant Statistician Dorothy G. Wiehl for help in tabulations and for suggestions, and to Dr R H. Riley, of the Maryland State department of health, for a summarization of the reports of diseases notified in Hagerstown during the period concerned.

CURRENT WORLD PREVALENCE OF DISEASE

REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED AUGUST 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT[1]

Cholera diminished rapidly during July in all the principal ports of the Far East except in Shanghai, where a sudden outbreak began the middle of the month and 314 cases were reported in the one week, July 25–31, according to information contained in the August Epidemiological Report published at Geneva by the health section of the League of Nations' secretariat The weekly cases (or deaths) reported at the various ports are given in Table 1.

TABLE 1.—*Cholera prevalence reported in the principal ports of the Far East from June 26 to July 31, 1926*

City	Week ended—					
	June 26	July 3	July 10	July 17	July 24	July 31
Bombay (deaths)	0	0	0	0	1	1
Calcutta (deaths)	41	45	0	0	0	0
Negapatam (deaths)	23	7	3	2	1	0
Vizagapatam (deaths)	0	0	0	0	1	0
Rangoon (deaths)	12	6	11	7	1	1
Singapore (cases)	0	0	1	0	0	0
Bangkok (cases)	56	36	18	20	10	5
Saigon and Cholon (cases)	5	32	8	3	0	0
Haiphong (cases)	42	17	19	3	0	0
Shanghai (cases)	0	0	0	37	29	314

The outbreak of cholera in Kwang-Chow-Wan in June, with 70 cases between June 11 and 30, seems not to have spread, as no cases were reported in the first 20 days of July. In French Indo-China a slight decline is noted in July, when 1,528 cases of cholera were reported in the first 20 days as compared with 1,786 cases in the preceding 20 days

Plague.—The prevalence of plague in Africa in the first half of 1926 is shown in Table 2.

TABLE 2—*Plague cases reported in Africa during 1926*

Month	Kenya	Nigeria	Senegal	Tunisia	Madagascar	Union of South Africa	4-week periods ended—	Uganda[a]	Egypt[a]

June	79			104	66		June 19	[b] 237	37
July				22					

[a] The data for Uganda and Egypt refer to periods of 4 weeks

[b] For 3 weeks only

[1] From the Office of Statistical Investigations, U. S. Public Health Service.

In Egypt 104 plague cases were reported from January 1 to July 22, 1926, as compared with 84 cases reported in the corresponding period of 1925, indicating, however, a very favorable plague situation. During the three weeks from July 2 to 22, 12 cases and 6 deaths were reported, with one case at Alexandria and the others in inland Provinces.

In the Dutch East Indies the plague deaths slightly decreased at the end of May and 167 deaths were reported in the three weeks ended June 5, as compared with 218 in the preceding three weeks

The plague outbreak at Baghdad continued to decline during June, and 15 cases were reported in the town in the two weeks ended July 3, as against 31 in the preceding two weeks.

In French Indo-China there were 9 cases of plague between July 1 and 20, of which 4 were at Saigon, 2 in Chaudoc (Cochin-China), 1 in Pnom-Penh, and 2 in Kandal (Cambodia). The plague incidence during the first five months of 1926 was less than in 1925, but in June and July it exceeded that in the corresponding period of 1925.

Plague cases reported in Indo-China, January–July, 1925 and 1926

Year	Jan	Feb	Mar	Apr	May	June	July
1925	5	--------	18	23	21	10	8
1926	2	7	7	13	3	22	[1] 9

[1] For 20 days only

At Kwang-Chow-Wan, 19 cases of plague were notified in the 10-day period June 21–30, and 18 during the preceding 10 days.

Reports from South American countries showed 34 cases of plague with 6 deaths during June in Peru, 2 cases at Guayaquil, Ecuador, in June, and 1 death at Sao Paulo, Brazil, in the week April 19–25.

Yellow fever.—The following cases of yellow fever are reported: Gold Coast, 3 cases and 1 death during April and 3 cases and 2 deaths during May; Bahia, Brazil, 2 cases and 2 deaths from May 2 to 15.

Typhus.—Among the European countries from which typhus is still reported, European Russia, Poland, Latvia, the Kingdom of the Serbs, Croats, and Slovenes, and Greece showed a considerably lower prevalence for the first six months of 1926 than for the preceding six-month period On the other hand, the prevalence during this period was higher in Czechoslovakia, Lithuania, Rumania, and Bulgaria. In Italy, where only one case had been reported during the period 1922–1925, 31 cases occurred in the first half of 1926 in Naples.

The incidence of typhus in African countries during the first half of 1926 is compared with 1925 in Table 3. The incidence was lower

in 1926 in Algeria, Egypt, and Basutoland, about the same in Tunisia and the Union of South Africa, and somewhat higher in 1926 in Morocco.

TABLE 3.—*Cases of typhus notified in various African countries, 1925 and 1926*

Month	Algeria		Morocco		Tunisia		South Africa		4-week period	Basutoland		Egypt	
	1925	1926	1925	1926	1925	1926	1925	1926		1925	1926	1925	1926

May	97	55	59	115	139	43	92	70	V	3	0	292	171
June	114	33	59	12	89	22	66	------	VI	2	------	254	------

Smallpox.—"The usual seasonal lull in smallpox incidence is apparent in the reports from nearly all countries," states the Report. "In northern England, however, while the incidence has decreased as compared to the earlier weeks of the present year, the number of cases reported during June and the early part of July represents an increase over the number of cases notified in corresponding periods of the last two years.

"The unusual prevalence in Japan, noted in previous reports of this year, shows signs of diminution. In India, the first half of the year has been marked by an incidence and mortality from smallpox greater than in recent years; Orissa, Bengal, and the central Provinces suffered most, the situation being relatively favorable in other districts."

Dysentery and enteric fever.—The reports available in the August Epidemiological Report, which refer to the month of June or the first half of July for the most part, did not to date indicate much seasonal rise in the incidence of either dysentery or enteric fever. On the whole, the incidence of these two diseases during the first six months of the present year compared very favorably with the preceding year.

Some increase in dysentery was noted in the reports for Germany, Greece, Japan, Korea, and Palestine.

Malaria.—There were 349,126 cases of malaria reported in European Russia, exclusive of the Ukraine, in the first quarter of 1926 as compared with 412,275 cases in the first quarter of 1925. A lower prevalence was reported in all the different geographical regions, except the Central Black Earth and the Middle and Lower Volga Regions, where the numbers of cases during the first quarter were slightly higher than in 1925. In the Ukraine, 41,770 cases were reported in the first quarter of 1926, less than half the reported incidence in the corresponding period of 1925.

Acute poliomyelitis.—The latest reports, relating to the last week of June and the first two weeks of July, show a slightly increased number of cases of acute poliomyelitis in England, Norway, Sweden, Germany, Italy, and the United States, thus indicating the approaching summer increase of this disease.

Cerebrospinal meningitis—As to epidemic cerebrospinal meningitis, a slight decline is to be noted in the last reports from Sweden; England and Wales, Holland, Austria, and Italy, while a comparatively higher incidence has been reported from Czechoslovakia, Germany, and Poland.

Communicable diseases in China.—The Report this month gives an interesting summary of the results of the efforts of Dr Tsefang F. Huang, Chief of the Department of Administration of the National Epidemic Prevention Bureau at Peking, to obtain information on the prevalence of certain communicable diseases in China Doctor Huang addressed letters to the practitioners of western medicine in the 18 Provinces of China and Manchuria, and inclosed post cards to be filled out and returned monthly. A large proportion of the physicians have been cooperating since May, 1925. The following summary, taken from the Report, was based on the information obtained by Doctor Huang for the 10 months, May, 1925, to February, 1926

It appears from these reports that plague was present (sporadic) in Manchuria during May and June, 1925, prevalent in Kwangtung Province during the same months, and endemic throughout the year in Fukien Province, the only district reporting plague in January-February, 1926 Infected rats were found throughout nearly the whole period in Fukien Province.

Cholera was notified from every reporting Province at some time during the 10 months It appears to have been most prevalent during August, September, and October, but too much reliance must not be placed upon this impression. The Provinces of Chekiang, Hunan, and Kiangsu appeared to suffer most. During January and February, 1926, the reports indicate a decrease, sporadic cases being notified from Anhwei, Honan, Kan-suh, and Kwangtung Provinces, while the disease was said to be prevalent in Chekiang and Shensi.

Smallpox was reported from every Province during the period; it was said to be epidemic in four Provinces during January and February, 1926, and prevalent in nearly all others

Dysentery was said to be present in all reporting Provinces, most prevalent, naturally, during the summer months. Typhus fever was reported from 14 Provinces during the first two months of 1926, and relapsing fever from 10 during the same period Other diseases for which returns were received were epidemic meningitis, diphtheria, and typhoid fever, the latter two being prevalent almost everywhere.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Relation of Summer Rainfall to Mosquito Prevalence.—Thomas J Headlee, New Jersey Agricultural Experiment Stations, New Brunswick, N. J, Bulletin 423, December, 1925, pp. 3–14. (Abstract by J. A Le Prince.)

In this article the writer answers the question, In the absence of mosquitoes why do we continue to have antimosquito work?

Only by constant work can the mosquito pest be held in subjection. Basic facts in mosquito life history are given. Suitable temperature, larval food, and light to support that food, are essentials. Rainfall is a basic factor for larval development in upland, and tide a basic factor on salt marshes Extreme acidity or alkalinity is fatal to larval development. The type of tide most likely to result in mosquito broods is one which runs just high enough to send the water creeping through the grass and filling the depressions The grass acts as a screen and prevents fish from accompanying the creeping water into the depressions.

Flooding of stream channels in the uplands often destroys mosquito breeding, but the net result of heavy rainfall is enormous increase in water accumulations in which larvae can develop Studies of mosquito prevalence indicate distinctly that the number of mosquitoes varies inversely as the intensiveness of antimosquito work.

Malarial Fevers in the United States Army and at Selected Stations.—Maj. Albert G. Love. *Military Surgeon*, Vol. 58, No. 6, June, 1926, pp. 593–610; Vol. 59, No. 1, July, 1926, pp. 69–95. (Abstract by L. D. Fricks.)

This is a brief historical review of malarial fevers in the United States Army from the beginning of the nineteenth century, as compiled from the records of the Surgeon General's office and reports from Army surgeons at different stations. All of these reports indicate a pronounced reduction in malaria in the United States Army during the period covered.

One hundred years ago malarial fevers were responsible for more than 25 per cent of all sick admissions to Army hospitals Since the World War malaria has been responsible for only 1 per cent of admissions In 1841, during the Seminole War, 50 per cent of admissions to post hospitals were attributed to malaria; during the Mexican War, 25 per cent; during the Civil War, 23 per cent; during the Spanish-American War, 23 per cent; and during the World War, one-half of 1 per cent.

In past years epidemic malaria was reported among soldiers stationed at Fort Wayne, Mich. (Detroit), Fort Hamilton, N. Y., and Columbus Barracks, Ohio. In recent years malaria has been controlled on all Army posts in the United States by suitable antimosquito measures.

Protection of Highway Water Supplies.—Earle L. Waterman, Professor of Sanitary Engineering, University of Iowa, Iowa City, Iowa *American Journal of Public Health,* Vol. 16, No. 3, March, 1926, pp 250–256. (Abstract by H. B Hommon.)

By means of a questionnaire, the status of roadside water supply work in 40 States was ascertained In 10 States definite programs for marking safe sources of water supply along the principal highways are being carried out. Sanitary surveys and bacteriological examinations of roadside supplies are made in five States, but no signs are posted In three States water supplies of tourist camps are supervised by State health departments, and preliminary investigations are under way in two States Twenty States reported that no special attempt had been made to supervise roadside water supplies Many State health departments favor the general plan of supervising roadside water supplies without the use of signs, while others favor posting only the unsafe sources of supply.

Discussion by W H Dittoe, formerly State sanitary engineer, Ohio State Department of Health· The Ohio State Department of Health started a systematic survey of water supplies available to the motoring public in February, 1924 Between that date and October, 1925, 1,850 miles of highways were covered and approximately 1,450 water supplies examined. Of the total only 105 were given the "Seal of safety," and of this number, 102 were drilled wells, 2 were springs, and 1 was a dug well A large percentage of the 1,300 sources which were unsatisfactory could be made approved sources with improvement made in their protection.

Rural Water Supplies may Appear Deceptively Pure.—Jack J. Hinman, jr., Associate Professor of Sanitation, University of Iowa, Iowa City, Iowa *The Nation's Health,* Vol. 8, No. 7, July 15, 1926, pp 465–467. (Abstract by Paul S. Fox.)

Rural water supplies may be divided into two classes: The supply for domestic use; and the supply for farm animals, irrigation, and other uses. Domestic water is usually obtained from wells and springs or cisterns Water for animals is commonly obtained from streams or ponds. It would be much better if farm animals were supplied with a good ground water, since surface water may be polluted to such extent as actually to endanger the health of the animals

Analyses of water from private sources 1915–1924, inclusive, were as follows:

Source	Per cent satisfactory
Shallow wells	18 14
Deep wells	68 19
Springs	29 09

The article contains the usual advice in regard to the protection of wells, springs, and cisterns, with a number of illustrations

Sterilization of Water by Liquid Chlorine.—J. M Mathew *The Commonwealth Engineer* (Australia), Vol. 13, No. 1, August 1, 1925, pp 30–33 (Abstract by Sol Pincus.)

An account and description of equipment is given of what appears to be the first use of liquid chlorine for the treatment of a public water supply in Australia The purposes and methods of chlorination are reviewed and reference to its widespread use in water purification in the United States and Canada is made.

The author describes the tests made in applying liquid chlorine through American-made control apparatus to a surface water supply which at times was somewhat turbid and contained the wash from a populated watershed. The results were in agreement with the American experience. The addition of chlorine of 0.4 p. p. m. under moderately favorable conditions gave a water of high degree of purity. The colorimetric test with orthotoluidine giving a residual of 0.1 to 0.2 after 10 minutes was a satisfactory guarantee. Such a dosage, except for local or seasonal modification, would have no adverse effect on the taste of the water.

VENEREAL DISEASE MANUAL FOR SOCIAL AND CORRECTIVE AGENCIES

A new publication entitled "Venereal Disease Manual for Social and Corrective Agencies" has been recently prepared by the United States Public Health Service.

There is a definite relationship between venereal diseases and insanity, dependency, delinquency, crime, and other conditions affecting the social structure. The Public Health Service has had an increasing demand from many individuals and organizations interested in the various branches of social welfare for authentic and comprehensive information concerning the social and economic aspects of the venereal diseases. It was to meet this demand for information that the publication was prepared

In addition to giving fundamental information on the medical aspects of the venereal diseases, their relief and prevention, the manual deals with the socio-economic relationships of these diseases and has chapters on the following subjects: The venereal diseases and the community, sex education, legal aspects of venereal disease control, sex morality and the law. juvenile delinquency, aids in conditioning behavior.

The book should be of especial value to the following groups: Court officials; social workers; police and probation officers; nurses, visiting

teachers, nurses' training schools and schools of social work; superintendents and matrons of homes for the dependent, delinquent, and defective classes.

The publication is bound in green buckram, and owing to the cost of printing and binding it will not be possible for the Public Health Service to distribute it free of charge It may be secured, however, from the Superintendent of Documents, Government Printing Office, Washington, D C , at 50 cents per copy.

DEATHS DURING WEEK ENDED SEPTEMBER 25, 1926

Summary of information received by telegraph from industrial insurance companies for week ended September 25, 1926, and corresponding week of 1925 (From the Weekly Health Index, September 29, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Sept 25, 1926	Corresponding week, 1925

[1] Annual rate per 1,000 population

[2] Deaths under 1 year per 1,000 births Cities left blank are not in registration area for births

[3] Data for 64 cities

[4] Deaths for week ended Friday, Sept 24, 1926

[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population Atlanta, 31, Baltimore, 15, Birmingham, 39, Dallas, 15, Fort Worth, 14, Houston, 25, Indianapolis, 11, Kansas City, Kans , 14, Louisville, 17, Memphis, 38, Nashville, 30, New Orleans, 26, Norfolk, 38, Richmond, 32, and Washington, D. C , 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

Washington	10	68	8		57		4	98	61	64

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria—For the week ended September 18, 1926, 38 States reported 1,058 cases of diphtheria. For the week ended September 19, 1925, the same States reported 1,095 cases of this disease. Ninety-seven cities, situated in all parts of the country and having an aggregate population of more than 30,100,000, reported 484 cases of diphtheria for the week ended September 18, 1926 Last year for the corresponding week they reported 537 cases. The estimated expectancy for these cities was 708 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics

Measles.—Thirty-five States reported 637 cases of measles for the week ended September 18, 1926, and 277 cases of this disease for the week ended September 19, 1925. Ninety-seven cities reported 160 cases of measles for the week this year, and 164 cases last year

Poliomyelitis.—The health officers of 38 States reported 115 cases of poliomyelitis for the week ended September 18, 1926. The same States reported 275 cases for the week ended September 19, 1925.

Scarlet fever—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 1,044 cases, last year, 831 cases, 97 cities—this year, 386 cases, last year, 343 cases, estimated expectancy, 361 cases.

Smallpox—For the week ended September 18, 1926, 38 States reported 98 cases of smallpox Last year for the corresponding week they reported 119 cases. Ninety-seven cities reported smallpox for the week as follows. 1926, 6 cases, 1925, 34 cases, estimated expectancy, 23 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever—One thousand three hundred and thirty-six cases of typhoid fever were reported for the week ended September 18, 1926, by 38 States. For the corresponding week of 1925 the same States reported 1,190 cases of this disease. Ninety-seven cities reported 307 cases of typhoid fever for the week this year and 281 cases for the corresponding week last year. The estimated expectancy for these cities was 240 cases.

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 91 cities, with a population of more than 29,480,000, as follows: 1926, 323 deaths; 1925, 358 deaths.

City reports for week ended September 18, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Dengue, 11 cases at Charleston, S. C.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended September 18, 1926, compared with those for a like period ended September 19, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925, and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more

than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, August 15 to September 18, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

PLAGUE ON VESSEL

Steamship "Zaria"—At Liverpool, England, from Lagos, Nigeria, Africa—On September 12, 1926, the steamship *Zaria* arrived at Liverpool, England, from Lagos, Nigeria, with history of two fatal cases of plague occurring on board at sea in the persons of two colored firemen. It was not ascertained whether these firemen had been ashore at African ports The steamship *Zaria* was stated to be a passenger ship and freighter plying between Liverpool and the West Coast of Africa, with stops at several African ports. On arrival at Liverpool four dead rats from the ship were found plague infected

THE FAR EAST

Report for week ended September 4, 1926—The following report for the week ended September 4, 1926, was transmitted by the far eastern bureau of the secretariat of the health section of the League of Nations, located at Singapore, to the headquarters at Geneva:

Maritime towns	Plague		Cholera		Smallpox	
	Cases	Deaths	Cases	Deaths	Cases	Deaths

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Aden.
Iraq.—Basra.
British India.—Karachi, Chittagong, Cochin, Negapatam, Tuticorin.

Ceylon.—Colombo

Federated Malay States.—Port Swettenham

Straits Settlements.—Penang, Singapore

Dutch East Indies.—Batavia, Surabaya, Samarang, Cheribon, Belawan Deli, Palembang, Sabang, Makassar, Banjermasin, Tarakan, Padang, Samarinda, Pontianak, Menado

Sarawak.—Kuching

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao

Portuguese Timor.—Dilly

Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga

French Indo-China.—Saigon and Cholon, Turane, Haiphong.

China.—Hongkong

Formosa.—Keelung

Japan.—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki

Korea.—Chemulpo, Fusan

Manchuria.—Antung, Mukden, Changchun.

Kwantung.—Port Arthur

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.

New Guinea.—Port Moresby.

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.

New Caledonia.—Noumea

Fiji.—Suva

Hawaii.—Honolulu.

Society Islands.—Papeete

AFRICA

Egypt.—Port Said, Suez

Anglo-Egyptian Sudan.—Port Sudan, Suakin.

Eritrea.—Massaua

French Somaliland.—Jibuti

British Somaliland.—Berbera

Italian Somaliland.—Mogadiscio

Kenya.—Mombasa

Zanzibar.—Zanzibar

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria

Mauritius.—Port Louis

Portuguese East Africa.—Mozambique, Beira, Lourenço Marques

Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Calcutta

Dutch East Indies.—Balik-Papan

ALGERIA

Plague—Philippeville—September 7, 1926.—Under date of September 7, 1926, a case of plague was reported at Philippeville, Algeria.

BRAZIL

Leprosy—Rio Grande do Sul.—Information received under date of August 21, 1926, shows leprosy present in the State of Rio Grande do Sul, Brazil, and to be increasing in prevalence.

Smallpox—Rio de Janeiro—August 15–September 4, 1926—Smallpox continued to be reported at Rio de Janeiro, with 786 cases, 406 deaths reported for the three weeks ended September 4, 1926.

CANADA

Communicable diseases—Week ended September 18, 1926—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended September 18, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				3	1	1		5
Poliomyelitis				6				6
Smallpox				8		5	9	22
Typhoid fever	3	11	8	30	6	3	6	67

CHINA

Cholera—Amoy—August 8–21, 1926—During the two weeks ended August 21, 1926, 13 cases of cholera were reported at Amoy, China. The disease was stated to be present in epidemic form.

JAPAN

Summary of cholera—September 10, 1926.—A total of 35 cases of cholera has been reported in Japan to September 10, 1926. The greatest number of cases occurred in Kagakawa ken, viz, 8; in Kanagawa ken, including Yokohama, 3 cases, in Osaka, 6; in Hyogo and Ookayama kens, 7 cases each. In Wakayama ken two cases were reported, and in Hiroshima and Kochi one case each.

MALTA

Communicable diseases—August, 1926—During the month of August, 1926, communicable diseases were reported in the island of Malta as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	4	Pneumonia	1
Chicken pox	1	Puerperal fever	3
Diphtheria	6	Trachoma	99
Erysipelas	12	Tuberculosis	14
Lethargic encephalitis	3	Typhoid fever	32
Malta fever	70	Whooping cough	6
Measles	30		

Population, civil, estimated, 223,088

UNION OF SOUTH AFRICA

Plague—Cape Province—August 14, 1926—During the week ended August 14, 1926, plague was reported present in the Cape Province, Union of South Africa, with one case, white, occurring in Calvinia District and one fatal case, native, in Maraisburg District. Both cases were on farms

Area of rodent infection—Natural defenses—Measures proposed.—The known area of plague infection in veld rodents, affecting chiefly Namaqua gerbilles (jerboa) and Cape hares, in the northwestern section of the Cape Province, has been stated to extend to the south and west as far as Calvinia and Nieuwhoudtville and thence southward along the coastal belt to the Cape Peninsula The Roggeveld and Cedarberg Mountains and the Doorn and Olifants Rivers, with their irrigation canals, form natural barriers to spread of the infection It is proposed to supplement these natural defenses by clearing of rodents a belt of country about 2 miles wide and 6 miles long between the Doorn River and Klaver, and to similarly clear of rodents the strip, to the extent of about a mile wide, between the Olifants River and the irrigation canal on the right bank, to a point beyond which the river is impassable to rodents

VIRGIN ISLANDS

Communicable diseases—August, 1926.—During the month of August, 1926, communicable diseases were reported in the Virgin Islands of the United States as follows:

Island and disease	Cases	Remarks
St Thomas and St. John		
Chancroid	9	Imported, 2, from St. Croix
Gonorrhea	9	Imported, 2—St Croix, 1, San Juan, P R, 1.
Syphilis	11	Secondary, 7, tertiary, 2, of eye, 1; cerebrum, 1
Tetanus	1	
Uncinariasis	2	Imported, 1
St Croix		
Gonorrhea	1	
Filariasis	1	Bancrofti

UNITED STATES PUBLIC HEALTH SERVICE.

HUGH S. CUMMING, *Surgeon General.*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C. C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 — OCTOBER 15, 1926 — NO. 42

DEATH RATE FROM TUBERCULOSIS DECREASING

Lower death rates from tuberculosis (all forms) were registered in 1924 than in 1900, for each age period for both sexes, in the Registration States of 1900, as shown by figures recently issued by the Department of Commerce. The amount of this decline in death rates ranged from 73 per cent for females under 1 year of age to 37 per cent for females aged 15 to 19 years. Specific rates per 100,000 population at each age period are given in the accompanying table.

This decline in tuberculosis death rates is not limited to the United States Similar declines are recorded in the death rates of England and Wales. A comparison of the 1924 death rates from tuberculosis (all forms) for England and Wales with the corresponding 1924 rates for the United States Registration States of 1900 reveals lower rates in the United States for each age period up to age 55 for each sex The greatest per cent difference up to age 55 was for males aged 5 to 9 years, the respective rates for the two countries being 37 for England and Wales and 15 for the United States, the latter rate being 59 per cent lower than the rate for England and Wales The least per cent difference up to age 55 was for females aged 20 to 24, the respective rates for the two countries being 153 for England and Wales and 146 for the United States, the latter rate being 19 per cent lower than the rate for England and Wales Comparisons of the tuberculosis death rates for the two countries for ages above 55 show much lower rates in England and Wales than in this country, so much lower in fact that apparently the only explanation is a tendency in England and Wales to certify at the older ages bronchitis as the cause of death instead of tuberculosis.

Death rates for tuberculosis, by sex and age groups, in the registration States of 1900

Age period	Death rate for tuberculosis (all forms) per 100,000 population in the registration States of 1900							
	1900		1910		1920		1924	
	Male	Female	Male	Female	Male	Female	Male	Female

PUBLIC HEALTH ENGINEERING ABSTRACTS

Housing Methods and Death Rate Variations Correlate. *The Nation's Health*, Vol. 8, No 6, June 15, 1926, pp. 425–426. (Abstract by A L Dopmeyer.)

In this short article are analyzed the results of a study by Dr. A. K Chalmers (*Proc. Roy Soc. Med*, March, 1926, pp. 13–22) to determine the probable effects on the health of the community produced by living in tenements as compared to cottages The comparison is made between England and Scotland, the general practice of the people of England in the past having been to live in cottages, and that of the people of Scotland to live in tenements.

According to Doctor Chalmers, dwellers in tenements in Scotland show a much higher death rate, particularly from communicable diseases, than people living in cottages in England; in fact, Scotland shows a higher death rate for each sex at all ages A table shows comparative death rates between Scotland and England, and a specific comparison is made between Manchester, a "city of cottages," and Glasgow for the years between 1914–1922.

Incidentally, England is said to be attempting to relieve its housing shortage by building tenements and Scotland by building cottages, in each case, the method of housing of which the nation knows least.

Pollution of Water Supplies By Wastes from Canneries and Dairies in Iowa. J. H. Buchanan, Associate Professor of Sanitation Chemistry, Iowa State College, Ames, Iowa. *Journal American*

Water Works Association, Vol. 15, No 5, May, 1926, pp 527–530. (Abstract by Sol Pincus)

The stream-pollution problem of Iowa has become serious owing to the centralization of manufacturing plants producing organic wastes, particularly in the corn-canning industry and in the dairy industry It is pointed out that the corn-canning and creamery wastes differ from domestic sewage, as the fermentation of considerable quantities of carbohydrates in the former wastes results in very markedly increasing the acidity of the streams. Instances are given in which the corn-canning waste effected an increase of acidity in the stream of nearly one hundred fold. With the creamery wastes the effect of increase of acidity is also encountered, as well as a great increase in organic matter

The increase in acidity would be an important factor in the suitability of a stream for public water-supply purposes, on account of the corrosive nature of the acid water and the difficulty that would be experienced in the chemical process of purification

Schenectady Sewage-Treatment Plant Markets Its Sewage Sludge. Anon *Health News*, New York State Health Department, Vol 3, No. 22, May 31, 1926. p. 86 (Abstract by Isador W Mendelsohn)

In little over a year 2,500 cubic yards of dried Imhoff tank sludge from the Schenectady (N Y) sewage-disposal plant has been sold to the farmers of the county at 10 to 25 cents per load at the plant The farmers cart the material in trucks and farm wagons, the average haul being 6 miles, the longest 14 All types of crops were benefited and equal success was reported on both sandy and clayey soils.

The plan for selling the sludge is very interesting and can be adapted to other places. It included (1) advertisement of the fertilizer value of the sludge by the local farm bureau association in the local press and the farm bureau periodical; (2) form letters mailed by the bureau to its members; (3) exhibits at meetings of market gardeners; (4) spread of results of analysis of sludge samples by Cornell University among farmers.

COURT DECISIONS RELATING TO PUBLIC HEALTH

City, not county, held liable for expense of free vaccination.—(Michigan Supreme Court; Keho et al. *v.* Board of Auditors of Bay County, 209 N. W. 163; decided June 7, 1926) To prevent the spread of smallpox in Bay City, the plaintiffs, who were physicians constituting the board of health of the city, vaccinated approximately 10,000 school children, teachers, and janitors. Their bills were presented to the county board of auditors and disallowed because the auditors were of the opinion that the county was not liable. The circuit

court affirmed the auditors' action and on appeal to the supreme court the judgment of the circuit court was affirmed. The decision of the supreme court was based on section 5096 of the Compiled Laws, 1915, which provided that "the board of health of each city * * * may at any time direct its health officer or health physician to offer vaccination * * * with bovine vaccine virus * * * to every child and to all other persons, without cost to the person vaccinated * * * but at the expense of such city * * *."

Meat ordinance construed—(Colorado Supreme Court; Burtis *v.* City of Montrose, 247 P. 186; decided May 10, 1926.) A city ordinance prohibited any person from selling, or keeping or offering for sale, any meat not inspected by the city inspector, unless the meat bore the meat inspection brand or mark of the United States Department of Agriculture. The ordinance also fixed the charges for inspection The supreme court held that, where the meat handled by a person had been inspected and marked by the Federal Government, such person was expressly exempted from the payment of any inspection fee provided by the ordinance.

Tort action against Washington Suburban Sanitary Commission held not maintainable.—(District of Columbia Court of Appeals; Washington Suburban Sanitary Commission *v.* Magruder, 12 F. (2d) 832; decided May 3, 1926) The plaintiff in the lower court brought an action for damages against the Washington Suburban Sanitary Commission for personal injuries alleged to have been caused through the negligence of the defendant in constructing and laying a sewer. The court of appeals held that the action could not be maintained because the commission was a governmental agency created by a Maryland law and was without funds or power to raise same for the purpose of paying damages

Commitment of drug addicts under certain statute not warranted.—(New York Supreme Court; People ex rel. Sherwood et al. *v.* City of Buffalo et al., 216 N. Y. S. 468; decided March, 1926.) Where there was no statute making the use of habit-forming drugs unlawful, the supreme court held that the Buffalo city court could not commit persons to a hospital under a statute authorizing such commitment "for unlawfully using" habit-forming drugs. The court also held that such statute did not make the use of habit-forming drugs unlawful.

Migratory livestock act held unconstitutional—(Colorado Supreme Court; People *v.* Morgan, 246 P 1024; decided May 24, 1926.) The migratory livestock act of 1925 provided that "whenever any migratory livestock is driven into or pastured or suffered to range or graze in this State from an adjoining State, the owner thereof or his agent shall 10 days before crossing the State line notify the sheriff of the county into which such entry is made of such entry," and also

required the inspection of such livestock for communicable diseases. The collection of a certain fee for each animal was also prescribed. In a prosecution for a violation of the act, the supreme court in its opinion stated in part as follows:

Section 6 of the above act of the legislature provides, among other things, that it does not affect livestock owned by residents of this State which are ranged a portion of the year in adjoining States, or which are taken for shipment back into this State By sections 1, 2, and subsequent sections, the act is made to apply to migratory livestock driven into, or suffered to range or graze in, this State from adjoining States. In other words, one rule is made for residents of Colorado and another for nonresidents If inspection is necessary for the one, it is necessary for the other.

The above discrimination is repugnant to clause 1, section 2, article 4, of the Constitution of the United States, which entitles the citizens of each State to all privileges and immunities of citizens in the several States It is also contrary to that part of section 1 of the fourteenth amendment to the Constitution of the United States which forbids any State from making or enforcing any law abridging the privileges and immunities of the citizens of the United States.

The court held the entire act to be invalid

Enjoining of enforcement of slaughterhouse ordinance refused.—(Texas Court of Civil Appeals, City of Wichita Falls *v.* Roberson, 283 S W 870, decided March 6, 1926) The plaintiff in the lower court sought to enjoin the enforcement of an ordinance of the city of Wichita Falls relating to slaughterhouses. The ordinance was very detailed and regulated the construction, equipment, and sanitation of slaughterhouses, required the medical examination of employees, and prohibited the use or sale as food of any animal not slaughtered at a place such as prescribed by the ordinance. Other provisions relating to the subject were also contained in the ordinance. The court of civil appeals refused to grant the injunctive relief asked for, and stated as follows in the opinion:

We conclude that it can not be said that the ordinance invoked in this case, as a whole, is void or violative of any constitutional provision invoked, or that plaintiff's petition or the facts proven on the trial come within any exception to the general rule which denies equitable relief from the enforcement of a criminal statute.

Inspection fees, applicable to private meat markets and imposed by city ordinance, held excessive.—(Louisiana Supreme Court; City of Baton Rouge *v.* Sanchez, 108 So. 552; decided May 3, 1926.) An ordinance of the city of Baton Rouge provided, among other things, for the inspection of private meat markets and fixed the fees for such inspection at a certain amount for each animal, the amount varying with the kind of animal. The fees were on a daily basis, while the markets were inspected about twice a month. The defendant, the owner and operator of a private meat market, refused to pay an amount assessed against him in accordance with the schedule of fees contained in the ordinance, and the city brought suit to recover

the same. The legality of the ordinance was attacked on the ground that the fees, if construed as either a license or a tax, exceeded the maximum limits provided by the State constitution, and also on the ground that the fees were arbitrary, excessive, and exorbitant, and in no way related to the cost of inspection, but were in restraint of trade and an attempt on the part of the city to raise revenue under the guise of the police power. The evidence showed that the fees and charges assessed against the defendant, on a per annum basis, were far in excess of all of his State and parish taxes and licenses. The supreme court decided in favor of the defendant, and the ordinance, in so far as it attempted to impose the stated fees on private meat markets, was annulled. The following are portions from the court's opinion:

We would not be disposed to interfere with the exercise of the discretion vested in the council and to declare the ordinance illegal if it was made to appear that the fees demanded were for regulatory and inspection purposes, even though the city did incidentally derive a small revenue from such fees over and beyond the amount required to cover the cost and expense incident to the regulation and inspection of the markets

But the fees exacted under the ordinance are so patently out of proportion to, and so obviously in excess of, the amount necessary to meet the expense and cost of the service contemplated, that we are constrained to hold that the city went beyond its police power of regulation and that the exactions demanded constitute a source of revenue, are within the term "license or tax," and exceed the constitutional limitation

Town ordinance held valid in so far as making it unlawful to permit certain animals to pollute stream used as water supply.—(Utah Supreme Court, Town of Ophir *v* Ault, 247 P. 290; decided June 4, 1926.) One of the provisions of an ordinance of the town of Ophir made it unlawful to permit any cattle, horses, sheep, goats, or hogs to pollute any stream of water, used by the inhabitants of the town, anywhere within 10 miles above a point where said water was first taken by the town for domestic purposes. The defendant was charged with violating the above ordinance in that he permitted his sheep to pollute a stream used by the inhabitants of the town as a water supply and of which stream the town was part owner. The supreme court held that the town had statutory authority to enact an ordinance for the protection of its water supply, and that the ordinance in question was valid as far as the offense charged was concerned. The conviction of the defendant in the lower court was affirmed by the supreme court.

Occupational disease held not compensable under workmen's compensation act.—(Texas Commission of Appeals, Section B; Aetna Life Ins. Co. *v.* Graham et al, 284 S W. 931, decided June 9, 1926.) As a result of continued exposure to gases, fumes, etc., incident to her work, an employee of a shoe polish manufacturing company

contracted tuberculosis and died therefrom. In an action for compensation under the workmen's compensation act, the commission of appeals was of the opinion that recovery could not be had for an occupational or industrial disease The commission held that the employee in the instant case had suffered no accidental injury, and that, therefore, the claim was not compensable The commission recommended that judgment be rendered denying compensation, and the supreme court entered judgment as recommended.

THE NOTIFIABLE DISEASES

PREVALENCE DURING 1925 IN CITIES OF 10,000 TO 100,000 POPULATION

The tables shown on the following pages were compiled from data furnished by the health officers of cities. Requests for information were sent to all cities of the United States having 10,000 population or more. The data for cities having more than 100,000 population were published in the PUBLIC HEALTH REPORTS, volume 41, No. 38, September 17, 1926.

The following is a list of the diseases included.

Anthrax
Cerebrospinal fever.
Chicken pox.
Dengue.
Diphtheria.
Influenza
Lethargic encephalitis.
Malaria.
Measles.
Mumps.
Pellagra.
Pneumonia (all forms).
Poliomyelitis (infantile paralysis).
Rabies in animals
Rabies in man
Rocky Mountain spotted fever.
Scarlet fever
Septic sore throat
Smallpox
Tuberculosis (all forms and pulmonary)
Typhoid fever.
Typhus fever.
Whooping cough.

The present article contains reports from cities having between 10,000 and 100,000 population. It is believed that practically all of these cities are included which have records of morbidity from communicable diseases which are of value for statistical purposes.

The populations given and which were used in computing the rates were estimated as of July 1, 1925. Estimates of population by the Bureau of the Census are based upon the assumption that the annual increase in the population of any city since 1920 is equal to the increase between 1910 and 1920 as shown by the returns of the two Federal censuses. This method gives an estimate which is approximately correct for most of the cities In a few cases, however, where there is reason to believe that the results thus obtained are far from correct, no estimate is made. The number of cases and

deaths occurring from each disease in these cities is given but no rates are computed.

The estimated expectancy, given in the tables for some of the diseases, is the result of an attempt to ascertain from the experience of recent years how many cases of the disease under consideration might be expected in 1925 In most instances the estimated expectancy is the median number of cases reported by the city for the years 1918 to 1924, inclusive When several epidemics have occurred during these years, or when for other reasons the median is not satisfactory, epidemic years are excluded, and the estimated expectancy is the mean of the number of cases reported for the nonepidemic years. The aim has been to ascertain how many cases of each disease may reasonably be expected in the absence of epidemics

The column headed "Number of years" shows the number of years for which data are available for each city.

In comparing the figures for 1925 with the estimated expectancy, averages, or with reports for preceding years, it should be borne in mind that there has been a gradual improvement in the reporting of communicable diseases during the last few years. An increase in the number of cases reported may be due to better reporting of the particular disease rather than to an increase in the number of cases existing.

In studying these tables it should be kept in mind that a relatively large number of reported cases of a communicable disease as indicated by a high case rate (and more especially when accompanied by a relatively small number of deaths, as indicated by a low fatality rate) usually means that the health department of that city is active and that the cases of the disease are being well reported by the practicing physicians It does not usually mean that the disease is more prevalent in that city than in other cities. A high fatality rate may mean that the disease was unusually virulent in a city, that the physicians did not treat the disease in that city with the success usual elsewhere, or that the practicing physicians did not report all of their cases to the health department On the other hand, an unusually low fatality rate may be due to the fact that the disease in the city was unusually mild, that the physicians treated it with unusual success, that the practicing physicians reported their cases satisfactorily, or that the registration of deaths was incomplete or the assignment of the causes of death inaccurate.

Cities which did not report either cases or deaths of a certain disease in 1925 are not included in the table for that disease.

Reported Prevalence for the Year 1925

[1] Annual rate per 1,000 population
[2] Death under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 64 cities.
[4] Deaths for week ended Friday, Oct 1, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta 31, Baltimore 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Kansas City, Kans 14, Louisville 17, Memphis 38, Nashville 30, New Orleans [illegible], Norfolk 38, Richmond 32, and Washington, D. C. 25

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended October 9, 1926

ALABAMA	Cases
Chicken pox	1
Diphtheria	41
Influenza	25
Malaria	127
Measles	6
Mumps	4
Ophthalmia neonatorum	1
Pellagra	7
Pneumonia	22
Scarlet fever	13
Tuberculosis	33
Typhoid fever	63
Whooping cough	6

ARKANSAS	
Cerebrospinal meningitis	1
Chicken pox	13
Diphtheria	14
Hookworm disease	1
Influenza	18
Malaria	125
Mumps	8
Pellagra	11
Poliomyelitis	1
Scarlet fever	5
Tuberculosis	5
Typhoid fever	24
Whooping cough	25

COLORADO	
Chicken pox	8
Diphtheria	18
Measles	3
Mumps	2
Paratyphoid fever	1
Pneumonia	2
Scarlet fever	25
Septic sore throat	1
Tuberculosis	21
Typhoid fever	8
Vincent's angina	2
Whooping cough	3

CONNECTICUT	Cases
Cerebrospinal meningitis	1
Chicken pox	9
Conjunctivitis (infectious)	1

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week

State	Cerebrospinal meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
August, 1926										
Delaware		5					5	9	0	5
September, 1926										
Arizona	0	6			14		1	13	0	10
Connecticut	0	42	3	4	26		11	89	0	34
District of Columbia	0	48	1		3	3	1	25	0	24

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended September 25, 1926, 38 States reported 1,277 cases of diphtheria. For the week ended September 26, 1925, the same States reported 1,272 cases of this disease. Ninety-six cities, situated in all parts of the country and having an aggregate population of more than 29,600,000, reported 615 cases of diphtheria for the week ended September 25, 1926. Last year for the corresponding week they reported 541 cases. The estimated expectancy for these cities was 786 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-seven States reported 793 cases of measles for the week ended September 25, 1926, and 330 cases of this disease for the week ended September 26, 1925. Ninety-six cities reported 211 cases of measles for the week this year, and 193 cases last year.

Poliomyelitis.—The health officers of 38 States reported 117 cases of poliomyelitis for the week ended September 25, 1926 The same States reported 284 cases for the week ended September 26, 1925.

Scarlet fever—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 1,235 cases; last year, 1,018 cases; 96 cities—this year, 452 cases; last year, 327 cases; estimated expectancy, 404 cases.

Smallpox.—For the week ended September 25, 1926, 38 States reported 123 cases of smallpox. Last year for the corresponding week they reported 102 cases. Ninety-six cities reported smallpox for the week as follows: 1926, 17 cases; 1925, 31 cases; estimated expectancy, 22 cases. No deaths from smallpox were reported by these cities for the week this year

Typhoid fever.—One thousand two hundred and thirty-eight cases of typhoid fever were reported for the week ended September 25, 1926, by 38 States. For the corresponding week of 1925, the same States reported 1,222 cases of this disease. Ninety-six cities re-

ported 249 cases of typhoid fever for the week this year and 248 cases for the corresponding week last year. The estimated expectancy for these cities was 221 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 9[illegible] cities, with a population of more than 28,900,000 as follows: 1926, 39[illegible] deaths, 1925, 295 deaths.

City reports for week ended September 25, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended September 25, 1926, compared with those for a like period ended September 26, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, August 22 to September 25, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

CANADA

Communicable diseases—Week ended September 25, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended September 25, 1926 as follows:

Diseases	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	8							8
Lethargic encephalitis						2		2
Poliomyelitis				12				12
Smallpox				3	1		4	8
Typhoid fever	1	12	4	25	7	4	1	54

Communicable diseases—Ontario—September, 1926 (comparative) —During the month of September, 1926, communicable diseases were reported in the Province of Ontario, Canada, as follows:

Disease	September, 1926		September, 1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis	4		4	1
Chancroid	3			
Chicken pox	123		88	
Diphtheria	239	18	271	16
German measles	7		1	
Gonorrhea	133		134	
Influenza	6			10
Lethargic encephalitis			9	
Measles	149		59	
Mumps	15		29	
Pneumonia		88		85
Poliomyelitis	22		37	
Scarlet fever	141		162	5
Septic sore throat			4	
Smallpox	23		25	
Syphilis	89		70	
Tuberculosis	117	43	148	62
Typhoid fever	94	3	130	8
Whooping cough	232	10	295	7

Smallpox.—Smallpox was reported present in the Province of Ontario during the month of September, 1926, in 10 localities. The largest number of cases was reported at Peterboro, viz, 10.

Vital statistics—Quebec—July, 1926—Births and deaths in the Province of Quebec for the month of July have been reported as follows:

Estimated population	2,570,000
Births	6,702
Birth rate per 1,000 population	31.29
Deaths (all causes)	2,668
Death rate per 1,000 population	12.45
Deaths under 1 year	763
Infant mortality rate	113.84
Deaths from—	
Cancer	128
Cerebrospinal meningitis	13
Diabetes	26
Deaths from—Continued.	
Diphtheria	19
Heart diseases	326
Influenza	36
Measles	25
Scarlet fever	4
Syphilis	7
Tuberculosis (pulmonary)	216
Tuberculosis (other forms)	75
Typhoid fever	16
Whooping cough	30

CHINA

Cholera—Tsingtao—August 30, 1926.—On August 30, 1926, cholera was reported present at Tsingtao, China. The first case was reported in the person of an American, who died of the disease the day after his arrival in the city and is believed to have become infected en route to Tsingtao. The next occurrence was in the Japanese community, with about 10 fatalities. Among the Chinese population from 30 to 40 deaths from cholera were reported daily, the greater number occurring in villages in the immediate vicinity of the city. A second case in a foreigner occurred in a British subject.

Precautions against spread.—Cholera inoculation was administered to the police, military, and civil employees, but was not compulsory; orders were published forbidding use of uncooked food and fruits; quarantine supervision was exercised over arrivals from Amoy, Shanghai, and other ports in south China.

CHOSEN

Cholera—North Heian Province—September 9–16, 1926.—During the period September 9 to 16, 1926, 70 cases of cholera with 30 deaths, estimated, were reported in the North Heian Province, Chosen.

ESTHONIA

Communicable diseases—July, 1926.—During the month of July, 1926, communicable diseases were reported in the Republic of Esthonia as follows: Cases—diphtheria, 36; leprosy, 1; measles, 192; paratyphoid fever, 17; scarlet fever, 169; tuberculosis, 155, typhoid fever, 34. Population, 1,107,059.

JAMAICA

Smallpox (alastrim)—Other communicable diseases—August 1–28, 1926.—During the period August 1 to 28, 1926, 93 cases of smallpox, reported as alastrim, were reported in the island of Jamaica, occurring at localities other than Kingston. Cases of other communicable diseases were reported as follows:

Disease	Kingston	Other localities	Disease	Kingston	Other localities
Cerebrospinal meningitis		1	Scarlet fever	1	
Chicken pox		5	Tuberculosis (pulmonary)	7	37
Measles	3	22	Typhoid fever	9	89
Ophthalmia neonatorum		1	Yaws		2
Pneumonia		9			

PANAMA CANAL

Communicable diseases—August, 1926—During the month of August, 1926, communicable diseases were reported in the Canal Zone and at Colon and Panama, as follows:

Disease	Canal Zone		Colon		Panama		Infected in other localities		Total	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
Diphtheria	1		1		13	1	2		17	1
Dysentery	1				6	1		1	7	2
Hookworm disease					55	1			55	1
Leprosy		1								1
Malaria	139	1	5		17	3	32	2	193	6
Measles	1		3		23		2		29	
Pneumonia [1]		3		6		25		3		37
Tuberculosis [1]		4		6		22		3		35
Whooping cough	2		1		4		1		8	

[1] Only deaths reported.

PERU

Plague—August, 1926.—During the month of August, 1926, 21 cases of plague with 9 deaths were reported in Peru. The occurrence was in the Departments of Cajamarca and Lima and was distributed as follows: *Cajamarca*—In the Province of Contumaza, 1 case; *Lima*—Chancay Province, cases, 5, deaths, 2; Lima Province, at Chosica, cases, 6, deaths, 1; Lima City, cases, 2, deaths, 1; country district of Lima, cases, 7, deaths, 5.

SALVADOR

Quarantine against Guatemala—Smallpox.—According to information dated September 7, 1926, quarantine was in force at that date in the Republic of Salvador against arrivals from Guatemala on account of smallpox.

SIERRA LEONE

Sleeping sickness—August, 1926.—During the month of August, 1926, a case of sleeping sickness was reported in Sierra Leone, West Africa, occurring at Kpai, Kennema District.

UNION OF SOUTH AFRICA

Plague—Cape Province—Orange Free State—August 15–21, 1926.—During the week ended August 21, 1926, three cases of plague, occurring in Europeans, were reported in the Union of South Africa, of which two cases, fatal, occurred in the Cape Province, in Calvinia district, and one case in the Orange Free State, in Hoopstad district. The occurrence was on farms.

Smallpox.—New cases of smallpox were reported in Cape Province, August 15 to 21, 1926, in two districts.

Typhus fever—During the same period new cases of typhus fever were reported in the Transvaal Occurrence of typhus fever during the month of July, 1926, was reported as follows: *Cape Province*—Cases, 58, deaths, 15 *Natal*—Cases, 23, deaths 2 *Orange Free State*—Cases, 7 *Transvaal*—cases, 2. The occurrence was in the colored or native population

YUGOSLAVIA

Communicable diseases—August, 1926.—During the month of August, 1926, communicable diseases were reported in Yugoslavia as follows.

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	40	6	Measles	86	1
Cerebrospinal meningitis		1	Scarlet fever	326	31
Diphtheria	120	18	Tetanus	32	21
Dysentery	236	27	Typhoid fever	322	13
Glanders	2	2	Typhus fever	1	
Lethargic encephalitis	1		Whooping cough	215	153

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 OCTOBER 22, 1926 NO. 43

COOPERATIVE RURAL HEALTH WORK OF THE PUBLIC HEALTH SERVICE IN THE FISCAL YEAR 1926[1]

By L. L. Lumsden, Surgeon, United States Public Health Service

In the fiscal year ended June 30, 1926, the United States Public Health Service cooperated in demonstration projects in rural health work in 89 counties, or districts comparable to counties in 20 States, as follows

Alabama.—Colbert, Franklin, Jackson, Lauderdale, Lawrence, Limestone, Madison, Talladega, and Walker Counties

Arkansas.—Jefferson and Pulaski Counties

California.—San Diego and Santa Barbara Counties, and San Joaquin district

Georgia.—Baker, Decatur, Floyd, Glynn, Grady, Laurens, Miller, and Walker Counties

Illinois.—Crawford County.

Iowa.—Dubuque County

Kansas.—Jefferson, Lyon, McPherson, and Ottawa Counties.

Kentucky.—Mason County.

Louisiana.—La Fourche and Washington Parishes

Massachusetts.—Cape Cod district.

Mississippi.—Harrison, Hinds, and Washington Counties.

Missouri.—Dunklin, Gentry, Greene, Holt, Jackson, Marion, New Madrid, Nodaway, Pemiscot, Pettis, Polk, St. Francois, and St. Louis Counties.

Montana.—Cascade and Lewis and Clark Counties

New Mexico.—Bernalillo, Chaves, Dona Ana, Eddy, McKinley, Santa Fe, Union, and Valencia Counties.

North Carolina.—Edgecombe County.

Oklahoma.—Oklahoma, Okmulgee, and Ottawa Counties

South Carolina.—Georgetown County.

Tennessee.—Gibson, Hamilton, Morgan, Obion, Rhea, and Weakley Counties.

Virginia.—Carroll, Charlotte, Chesterfield, Greensville, Henry, Nansemond, Prince Edward, Pulaski, Roanoke, Smyth, Washington, and Wise Counties.

[1] This report applies to work in rural sanitation which is conducted in support of and as a part of whole-time local official health service It does not include all cooperative activities of the Public Health Service in rural communities

9276°—26——1

West Virginia.—Gilmer, Hancock, Harrison, Logan, Marion, Marshall, Preston, and Roane Counties.

The results were thoroughly in line with the conclusions in the reports on this activity for the fiscal years 1920,[2] 1921,[3] 1922,[4] 1923,[5] 1924,[6] and 1925.[7]

Plan of Work

The plan of the work was the same as that carried out in the six preceding fiscal years and is described in previous reports (Reprints Nos. 615, 699, 887, 964, and 1047.)

The authorization for this work is in the act of February 15, 1893 (ch. 114, 27 Stat. L. 449); the act of August 14, 1912 (ch. 288, 37 Stat. L. 309); and in the annual appropriation acts. The appropriation is specifically for "special studies of and demonstration work in rural sanitation."

The work is conducted in cooperation with State and local health authorities. It is made a part of a well-rounded comprehensive program of local health service. Experience has taught that under such arrangement the work can be carried out more economically and with better and more lasting results than if conducted as a separate specialized activity.

Through such connection as this with county health service projects, the Public Health Service can perform most economically and efficiently toward meeting its responsibility in helping prevent the spread of human infection in interstate traffic. The cooperative projects also furnish most favorable opportunities for studies, by the Public Health Service, "of the diseases of man and conditions influencing the propagation and spread thereof." Thus, this rural sanitation activity serves a number of important general purposes besides those specified in the appropriating act and, though very limited as yet in extent, it does contribute to that essential part of the work of the Federal Government to promote the general welfare.

The demonstration work in rural sanitation can not, under the provisions of the appropriating act, be conducted in a community unless the State, county, or municipality in which the community is located, agrees to pay at least one-half the expenses of such demonstration work. The funds provided by the State, county, and municipalities, together, for support of the average demonstration project far exceed the allotment from the Federal fund, and in almost all instances the appropriation from the local official sources (county, township, or town) covers considerably more than 50 per cent of the budget.

---

[2] Reprint No. 615, from Public Health Reports of Oct. 1, 1920, p. 15.
[3] Reprint No. 699, from Public Health Reports of Oct. 7, 1921, p. 17.
[4] Reprint No. 786, from Public Health Reports of Sept. 29, 1922, p. 22.
[5] Reprint No. 887, from Public Health Reports of Dec. 14, 1923, p. 24.
[6] Reprint No. 964, from Public Health Reports of Oct. 17, 1924, p. 23.
[7] Reprint No. 1047, from Public Health Reports of Oct. 23, 1925, p. 33.

The county, as a rule, is the unit for the work Under the cooperative arrangements, a good program of health work can be carried out in practically any rural county in the United States at a cost to the county readily within its means The average cooperative demonstration project is conducted on a cost basis of less than 50 cents per capita of population served and furnishes a striking example of efficiency with economy in public service By having all salient branches of health work for the community conducted under the direction of one head, the whole-time county health officer, who is given a status of field agent in the United States Public Health Service and in some of the States that of deputy State health officer, a maximum of service can be rendered with a minimum of overhead expense, lost motion, and friction Through good business management, every dollar invested in the enterprise can be made to yield a remarkable dividend in the protection and promotion of human health, and in a money saving to the community amounting to many times the cost of the service

This plan of cooperative rural health work has been evolved in the course of field experience and has been tested under a wide range of local conditions It seems applicable to all the rural districts of the United States. The provision of means for a reasonably rapid extension of this work would, according to all the evidence, prove highly advantageous from every standpoint—individual, community, State, and national

Appropriation

The appropriation for the rural sanitation work of the Public Health Service in the fiscal year 1926 was $75,000. Against the amount appropriated was set up a budget saving of $2,000. The unexpended balance from the operations of the preceding fiscal year was $10,055.55.[8] Thus, $83,055.55 was available.

Rural health work is applicable to communities in the United States comprising over 60 per cent (or over 70,000,000) of our total population Such communities include strictly country homes, incorporated towns and villages (with populations under 2,500), and, as the county is the logical political unit for official rural health-work administration, many towns and cities with populations from 2,500 to 50,000.

Under modern conditions of transportation and travel, rural and urban health conditions react upon each other. Therefore rural health work is of importance to our entire urban population. The sanitary quality of the tremendous volume of raw foods now shipped

[8] This balance was due not to an excessive amount of money being available but to temporary suspensions of the work and consequent decreased expenditure in some of the projects to which allotments had been made for the whole fiscal year 1925. Such suspensions are necessitated by various local circumstances and can not be anticipated when the contracts are made With the existing differences between the Federal fiscal year and the fiscal years of some of the States and localities in which the work is conducted it would not be practicable, without lessening the degree of economy striven for, to arrange contracts so that the allotment of Federal funds to every project would be expended exactly by the end of the Federal fiscal year

daily through interstate traffic is of keen importance, for both humane and business reasons, to our public and our private interests and should be enhanced and safeguarded by reasonably adequate, coordinated, joint activities of governmental agencies—local, State, and Federal To undertake sanitary control of traffic and travel by inspection and quarantine at our city borders and on our interstate lines now would be futile and ridiculous The efficient local health department, in doing its local work, performs duty of state-wide and nation-wide importance with which the State and the Federal health services are concerned Therefore it seems, from a sanitary standpoint, reasonable and proper for State and Federal agencies to encourage and help in the development and permanent maintenance of such departments

Less than 16 per cent of our rural population is as yet provided with local health service approaching adequacy under the direction of whole-time, local (county or district) health officers.[9] Because of lack of efficient, whole-time rural health service, infections of man are conveyed very frequently across interstate lines.

In our rural communities there are about 1,000,000 persons incapacitated all the time by illness, much of which is preventable; about 70 per cent of the school children are handicapped by physical defects, most of which are preventable or remediable; about 30 per cent of persons of military age are incapacitated for arduous productive labor or for general military duty, largely from preventable causes; and over 60 per cent of the men and women between 40 and 60 years of age are in serious need of physical reparation, largely as a result of preventable causes. In view of these conditions, there is no room for reasonable doubt about the need for more and better rural health service in this country.

The results of efficient health service are in life saving, disease prevention, health promotion, and economic saving The saving in dollars and cents amounts to many times over the cost of the service. Most of our rural county governments are not disposed to establish reasonably adequate county health service without an offer of financial assistance and competent counsel from some outside agency.

The amount appropriated for cooperative rural sanitation work in the average fiscal year of the last four years has been less than one forty-thousandth of the total congressional appropriation and less than 1 per cent of the sum appropriated for all the activities of the United States Public Health Service.

Expenditures

The expenditures in the fiscal year 1926 totaled $82,545 64 Of this sum $78,063.37 was expended in allotments for direct support of cooperative projects in counties or districts, and $4,482.27 was

[9] Reprint No 1079 from Public Health Reports of May 7, 1926.

expended for general administration, supervision of local projects, and special studies of the problem of rural sanitation.

With the increasing general interest in whole-time, rural health service, the demands upon the Public Health Service for cooperation far exceeded the money ($83,055 55) available for allotment In view of the overwhelming number of insistent and yet thoroughly reasonable requests from State and local authorities for cooperation, extreme care had to be exercised to prevent an overcommitment of the funds. The balance remaining at the end of the fiscal year was $509 91 [10]

For the support of the work in the 89 local projects the expenditures from all sources totaled $856,962 38 Of this sum $78,063 37 was allotted from the rural sanitation funds of the Public Health Service, an aggregate of $702,160 48 was derived from State, county, and municipal governmental sources, and $76,738 53 was derived from other sources, including local health associations, tuberculosis associations, local Red Cross chapters, the International Health Board, and the Children's Bureau of the United States Department of Labor Thus, this investment of the Federal funds appropriated for rural sanitation work was met with odds of almost 10 to 1

It is both significant and encouraging that organizations entering the public-health field to promote or conduct some specialized activity—such as typhoid fever prevention, hookworm control, tuberculosis prevention, trachoma control, malaria control, venereal-disease prevention, or advancement of child and maternity hygiene—realize, after practical experience, the advantage of dovetailing their specific activities in with and making them a part of a well-rounded, comprehensive program of local official health service under the immediate direction of a qualified, whole-time local health officer. Such arrangement is obviously in the interest of efficiency with economy in public health-work in our rural districts.

Compiled Data

The expenditures from the different sources for support of the cooperative demonstration projects, the scope, the principal activities, and some of the results of the work are presented in the accompanying tabular statement.

In attempting to measure the efficiency of health service, consideration is to be given to the local conditions—climatic, topographical, geographical, social, economic, and other—under which the work is done, the duration, nature, and scope of the activities, the cost of the service, and the results achieved. The 89 cooperative projects

[10] This balance will be reduced considerably by payment of bills yet to be received for freightage and telegraphing within the fiscal year.

listed in this tabular statement present a very wide range of local conditions. From equivalent, well-directed efforts much larger results are obtainable in one project than in another. Considering the cost of the service, the activities and results reported, and the findings from direct surveys of the situations by representatives of the Public Health Service and the State boards of health concerned, it is apparent that in the fiscal year 1926 some of the projects were highly successful, others were not up to reasonable expectations, and the average was good In rural health work, as in other business, the personal equation of the director of the unit is the main factor making for success or failure

A careful, analytical, and comparative study of the data in the table should be of interest to anyone competent to make such a study, and should be of especial interest to existing and prospective whole-time county (or local district) health officers.

The Cape Cod Project

The cooperative rural health work begun in May, 1921, under the direction of a whole-time district health officer in a group of the 15 towns (townships) in Cape Cod, Mass.,[11] has continued. In the first year of the work the number of towns participating was 10 and their pooled appropriations for support of the project was $5,100. In the fiscal year 1926 the number of towns participating was 10 and their appropriations aggregated $5,540. The survival of this cooperative project for a period of six years, under the New England town system of government, wherein the appropriation for the health service has to be authorized for each year by each town at a town meeting under a practically unanimous consent agreement of the citizens, is significant. This plan, with its demonstrated success on Cape Cod, seems to have a considerable range of applicability in those States in which the town, township, or borough instead of the county, is the rural unit of local government with respect to public health administration.

The Massachusetts Legislature in its 1925 session adopted an act enabling the board of commissioners of Barnstable County to establish a county health department. The Barnstable County health department, under the direction of a whole-time county health officer, is to begin operating in January, 1927. Thereafter the health service for Cape Cod will be supported with appropriations from the county treasury instead of pooled appropriations from the town treasuries. Any town on the cape can continue to maintain a town board of health, but the jurisdiction of the county health department will comprise the whole cape. The advantages of having the county as the unit for the local health administration are obvious.

The Barnstable County health department will be the first county health department established in New England. The precedent is of historic interest and is expected to prove of far-reaching practical importance.

Sanitary Officer Projects in Virginia and Tennessee Counties

The plan of special demonstration work in rural sanitation inaugurated in Virginia in the fiscal year 1920 was carried out in 10 counties[12] in that State and in 2 counties[13] in Tennessee in the fiscal year 1926.

[11] Reprint No 699, from Public Health Reports of Oct 7, 1921, pp 11, 12, Reprint No 788, from Public Health Reports of Sept 29, 1922, p 14; Reprint No 857, from Public Health Reports of Dec 14, 1923, p 16, Reprint No 964, from Public Health Reports of Oct 17, 1924, p 18, and Reprint No 1047, from Public Health Reports of Oct. 23, 1925, p 27.

[12] Carroll, Charlotte, Chesterfield, Greensville, Henry, Prince Edward, Pulaski, Roanoke, Smyth, and Washington.

[13] Morgan and Rhea.

This plan, which is described in previous reports,[14] continues to prove highly successful It meets remarkably well the situations in rural counties in which effective health work, if done at all, must be done on a low-cost basis, and in which outdoor sanitary measures are especially needed The cost for such service in the average county is about $2,750 a year The county sanitary officer is engaged on a whole-time basis He does not have to be a graduate in medicine or engineering, but he must be a trained, practical sanitarian. Along with his sanitary work, he carries out, with the active cooperation of the local physicians, most of the other activities expected of a whole-time county health officer with a medical degree

The results accomplished in the county sanitary officer projects become more impressive from year to year Some of these counties are now among the foremost in the list of rural counties in the United States presenting high-grade demonstrations in sanitary progress

This county sanitary officer plan after seven years of testing appears to offer to the counties to which it is appropriate as large a return on the investment for county health service as any other yet tried or proposed.

Three-County Project in Georgia

The project in the southwestern part of Georgia inaugurated in the fiscal year 1924 and described in the report for that year [15] and discussed in the report for the fiscal year 1925 [16] was continued in the fiscal year 1926. In this project one whole-time health officer, a physician with training in health work, serves as health officer of each of three adjacent counties Under his direction there is on duty in each of the three counties an assistant health officer who is a layman with practical training in sanitary work, and in one of the counties (Decatur) there is on duty also a county health nurse

The special purpose of this cooperative project is to demonstrate an economical plan of public-health administration adapted to counties with resources too limited for each to support readily a complete, whole-time county health department. The plan seems right in general principle, but the detailed execution of it is, of course, attended with some practical difficulties The health officer serves under three separate county governments. The budget has been inadequate, and it has been difficult to persuade the county authorities to keep up their disproportionately small part (50 per cent) of it. The counties which have been comprised in the project are comparatively small in area, population, and economic resources. The local

prevalence of malaria, hookworm disease, typhoid fever, and dysentery is high. Such diseases are impoverishing. Quite heavy expenditures have been made in these counties in recent years for improved roads and public schools. Both improvements were needed, but not so much as health work.

The money spent for 1 mile of paved road would buy adequate health service for three of the counties for a year At some of the handsomest, recently constructed public schools unprotected water supplies and grossly insanitary open toilets have been found in use. In some of the schools examined 100 per cent of the children have been found infested with hookworm, and in others over 40 per cent of the children have been found to be suffering from chronic malaria With such conditions the efficiency of the public-school system is necessarily low, and it seems certain that by diverting to efficient public-health work some of the money appropriated for schools—even to the extent, if necessary, of causing all the public schools to be closed for one year in five—a net gain could be realized in the specifically educational results from the public-school system

The program at the beginning of this project, adopted with a special view to popularizing the health service, was to concentrate the work largely upon personal service measures, such as hookworm treatments, antityphoid vaccination, and quininization for the prevention or cure of malaria That program has proved of doubtful advisability. The evidence now is that if from the beginning more work had been done to improve environmental sanitation to prevent disease and less time had been spent on the "personal service measures," the beneficial results would be larger, more obvious, and more lasting than those accomplished, and the appreciation of the value of the health service by the local citizens would be greater than it is now. Anyhow, two of the three counties in the original project have droppped out—Seminole after the first year and Miller after the second year. Fortunately, two other counties, Baker and Grady, adjacent to Decatur, the remaining one of the original three, promptly took the respective places of Seminole and Miller. Thus, the three-county project has been continued with vicissitudes, but without interruption

Since the latter part of the fiscal year 1926 the sanitary features of the program have had a large part of the attention and effort of the members of the health department force.

If this project survives and proves successful, as now seems definitely possible, the demonstration will be of great value both locally and generally, and will thoroughly justify the support which the State health department and the Public Health Service have given and may give to the undertaking.

Special Features

Of the many especially interesting features of the work in the 89 projects during the fiscal year 1926 the following are mentioned mainly for the purpose of illustration:

In the group of nine Virginia counties in which county sanitary officers were engaged throughout the fiscal year there was only one case of typhoid fever reported for the month of June, 1926 The remarkable reduction of typhoid fever prevalence in these counties is definitely attributable to sanitary improvements.

In Santa Barbara County, Calif, a case of malignant smallpox developed in the fall of 1925 in a resident who had contracted the infection while on a visit to Los Angeles The case was discovered promptly and the patient was isolated in the county hospital where he died a few days later The county health officer and the county sheriff together traced all contacts, vaccinated them, and placed them in isolation. Not a secondary case developed

In San Joaquin County, Calif, an outbreak of smallpox with 16 cases and 2 deaths in April, 1926, was promptly controlled by vaccination and isolation Over 17,000 residents of the county were vaccinated within a period of 60 days after the beginning of the outbreak. The district health officer reports that 70 to 75 per cent of the population of the county are now immunized by vaccination against smallpox.

In Lyon and Ottawa Counties, Kans., over 50 per cent of the school children are reported to have had complete immunization (toxin-antitoxin) treatments against diphtheria

In Washington Parish, La., with a population of 24,164, the specific immunizations within the fiscal year 1926 were 7,831 against smallpox, 2,794 against typhoid fever, and 2,024 against diphtheria

In Jackson County, Mo., a case of extreme club feet was found in a girl in the course of the physical examination of school children. The feet were twisted nearly all the way around. Although walking was very painful to this girl, she walked five days in the week to and from school at a distance of a mile and a quarter from her home. Her age was 17. She was one of a family of 11 children Her father was a farm laborer obtaining wages of only $40 a month The county health department made arrangements whereby this girl was sent to a hospital in Kansas City and there operated upon for relief of the condition. Among the well-to-do citizens of Jackson County who perhaps complain at times about the few cents per capita a year paid in taxation for the support of the health department, there is in all probability not one who would not gladly contribute a dollar or more for the relief of one case such as this girl's.

In New Madrid County, Mo., a tonsil and adenoid clinic was attended by 20 local practicing physicians who gave the clinic their

thorough support and helped to make it a complete success. Eighty cases were operated upon one day

In Cascade County, Mont., the health officer found, on his examination of children in the public schools in the spring of 1926, that among those in the seventh and eighth grades 78 8 per cent of the tonsils found enlarged or diseased at previous examination had been removed, and 61 6 per cent of the decayed teeth found the year before had been repaired or extracted

In Rhea County, Tenn., a case of virulent smallpox was discovered in a man who had come from Florida while in the early stage of the disease. Fifty-one contacts were vaccinated immediately and no other case developed.

In Laurens County, Ga , the grand jury, at its sitting in May, 1926, paid the following tribute to the work of the county health officer, who has no assistant in his department:

> We, the grand jury of Laurens County, received the sixth annual report of the county health officer, and after examining same wish to inform the people of Laurens County what a service is being rendered by this department The people of Laurens County get more in direct return from the health department than any other public office, and we wish to mention three or four items of work done last year Take typhoid vaccinations—3,339 persons immunized against typhoid fever at a minimum of $3 a treatment would be $10,017, also in 1924 there were 17 deaths from typhoid and in 1925 only 7
>
> We had several cases of smallpox in 1925, in fact two cases were found in the court house, and one was found in the grand jury room This situation was handled without any loss of time in court or on farm There were 3,967 persons vaccinated
>
> The laboratory handled 963 specimens
>
> Thirty-three mad dog treatments were administered at a minimum of $40 for each treatment This would amount to $1,320.
>
> Public water supplies, milk, and other food establishments are regularly inspected, also the first year the health department was organized we had about 20 or 30 cases of colitis in Dublin. It has been reduced to a minimum, only 9 deaths in the county in 1925
>
> Nine hundred and eighteen births and 463 deaths registered in 1925. The birth and death records are a great asset to the county.
>
> We, the grand jury, are unable to express our appreciation for the valuable work rendered by Dr O. H. Cheek, and the county is very fortunate in having him at the head of the health department, as we consider him second to none in the State In fact, he has given the people splendid service and his records are found complete in every detail.
>
> Again, we, the grand jury of Laurens County, commend this department for the efficient work done and wish this report to be recorded in the minutes of the clerk of the superior court

In McKinley County, N. Mex., the health department was remarkably successful in its nutritional work among school children in the session of 1925–26. Milk, cocoa, and sugar to augment school luncheons were furnished by local welfare organizations and individual citizens. One thousand eight hundred and seventy-five pupils were admitted to nutritional classes. All showed a steady

underweight, and by the end of April only 65 of them remained handicapped to a sufficient degree to require further special attention.

In Roane County, W. Va., the health department has done some exceedingly good publicity work. Among the measures adopted in the educational campaign was the sending to every school child a Christmas letter which was as follows:

ROANE COUNTY HEALTH DEPARTMENT,
Spencer, W. Va., December 21, 1925

DEAR ——: We are addressing this letter to you, because this is such a busy time of the year for grown-ups, especially for teachers. We are asking you to show this to your teacher and read it to your schoolmates.

How much we would like to enjoy Christmas with you! This being impossible, we want you to know we are thinking of each of you and wishing you the merriest Christmas you have ever had. We are sure Dear Old Santa Claus will be as good to you as he possibly can. Isn't he the jolly fellow? How we like his smiling face! Sometimes we wonder just what kind of a star would be on his weight chart. He always looks so "Happy," he must surely be "Healthy," no doubt his "Habits" are very good. There they are again, the three "Capital H's" that we like to talk about.

We will soon be through visiting all the schools in Roane County, and will be glad of that, for we want to hurry back to see all the good things you are doing for yourself.

We feel that many of you are "Happily" forming good "Health Habits," such as brushing your teeth, washing your hands with soap at school before dinner, being careful to use individual drinking cups, individual soap or liquid soap, and individual or paper towels, keeping your school floors oiled, helping your teacher keep the flag up when the weather permits, also helping to keep proper ventilation, not forgetting the water on the stove.

Many underweights are trying to catch up with the "Good Weight" boys and girls by bringing milk to drink at school. That's another good habit. Are any of you doing this?

We would like to hear from you. How about those windows to your body? We hope they have been helped and repaired by glasses where needed. Have any one of you taken trips to the Dentist to Save, Save, Save those precious six-year molar teeth? The first four teeth of the second set that are never shed, the four soldiers that stand guard in your mouth to keep the nice, new, shining teeth in regular order when they come, while your baby teeth are shed. Have you looked at them yourself in the looking-glass? After you are six years of age, they come to stay in your mouth unless you let them decay. They are also the foremen of your food-grinding factory, from center front, on each side, upper and lower. The sixth teeth in line are your own little white soldier friends. Look at them often and see what they are doing. Let the dentist save them for you if they should decay.

If any of you have baby brothers or sisters at home, let us know your father's name and address, also the name and age of the baby, so we can send them our baby book.

We wish each of you a Merry, Merry Christmas and a very Happy New Year.

Yours for health,

F. C. MAKEPEACE, M. D.,
County Health Officer, Field Agent, U. S. P. H. S.
CHARLOTTE KUNZE, R. N.,
County Health Nurse.

General Progress in Rural Health Work

Progress in the development of whole-time rural (county) health service in the United States continued in the fiscal year 1926. According to data [17] collected by the rural sanitation office from the State health departments, the number of counties, or equivalent divisions, provided with local health service reaching all rural sections thereof, under the direction of whole-time county or district health officers, was 307 at the beginning of the calendar year 1926 as against 280 at the beginning of the calendar year 1925, 250 at the beginning of the calendar year 1924, 230 at the beginning of the calendar year 1923, 202 at the beginning of the calendar year 1922, 161 at the beginning of the calendar year 1921, and 109 at the beginning of the calendar year 1920 The gain of 198 within this six-year period, though much less than it might have been had means been provided for a larger degree of cooperation from the Federal and State official agencies, is significant

The prospects are good for a better rate of progress in this vitally important field in the next six years. Our public-health administrators generally now appear convinced that local official health service under the direction of a whole-time local health officer is the most essential element in the development of an adequate system of effective and economical public-health service in the United States, and that most of the work of the Federal and State health agencies should be conducted with and through such local health departments The principle of cooperative rural health work appears sound in theory and obviously is successful in practice State health departments in increasing number from year to year are obtaining authorization and appropriations to enable them more nearly to do their due and proportionate part in the development and maintenance of whole-time county health service.

With a view to obtaining some idea of the popular attitude toward the participation of the United States Public Health Service in cooperative rural health work, copies of the report for the fiscal year 1925 were sent to a number of persons in representative positions. Included in the number were Senators and Representatives in Congress, governors of States, presiding officers of State legislatures, State superintendents of schools, presidents of State medical societies, presidents of State bankers' associations, State presidents of national parent-teachers' associations, State presidents of the general federation of women's clubs, district governors of Rotary, Lions, and Kiwanis Internationals, secretaries of chambers of commerce, and presidents and secretaries of national farm organizations. The reports were transmitted with a circular letter requesting an expression of opinion as to whether this activity of the U. S. Public Health

[17] Reprint No 1079 from Public Health Reports of May 7, 1926.

Service should be continued on the present scale, expanded, contracted, or discontinued. Two hundred and seventeen replies were received. Among them there were only six expressing an attitude of definite opposition to or of serious doubt as to the advisability of participation by the Federal Government in such work. Sixty-four were cordial but noncommittal. One hundred and forty-seven expressed the opinion that the cooperation of the U. S. Public Health Service in rural (county) health work should be continued either on its present or an expanded scale, and of these over two-thirds were definitely favorable to expansion.

Summary

The 89 cooperative projects in the fiscal year ended June 30, 1926, yielded results exceeding in value manyfold the cost of the work. Among the activities and results presented in the tabular statement (pp. 2387 to 2410), to which especial consideration may be given, are the following.

1. Public lectures presenting the principles and details of sanitation to over 402,600 persons.

2. Over 179,400 sanitary inspections of premises, with explanation of findings to occupants or owners of the properties.

3. Physical examination of over 235,000 school children, of whom over 148,000 were found to have incapacitating physical defects, with notification to parents or guardians of defects found.

4. Exclusion from public schools of 12,775 children affected with communicable diseases—such as diphtheria, scarlet fever, measles, whooping cough, scabies, and pediculosis—or presenting evidence of being carriers of the contagions of such diseases. This was brought about through active cooperation of school-teachers with the county health departments, and it must have been a very considerable factor in preventing widespread infection.

5. Thirty-three thousand one hundred and fourteen recorded treatments effecting correction of incapacitating physical defects among school children. These were brought about by written notification of defects found to parents or guardians, follow-up visits to homes of the children, making available proper clinical facilities, and other activities of the county or district health departments.

6. Bringing about treatments for correction of serious physical defects in 1,005 infants and 2,360 preschool children.

7. Treatments to correct iodine deficiency in 3,495 persons in endemic goiter districts.

8. Sixty thousand nine hundred and ninety-seven visits to homes of cases of communicable disease to advise and show the afflicted households how to prevent spread of the infections.

9. Six thousand five hundred and forty-six visits by health nurses to prenatal cases to advise and assist expectant mothers in carrying out hygienic and physiological measures making for healthy mothers and healthy babies

10 Instruction of 1,529 midwives in cleanly and careful methods.

11 Twenty-eight thousand three hundred and forty-nine infants and children of preschool age examined and over 34,200 home visits by health nurses or health officers to demonstrate hygienic measures for the promotion of the health and the protection of the lives of infants

12. Eighty thousand nine hundred and twelve persons inoculated for protection against typhoid fever.

13. One hundred and two thousand four hundred and eighty-seven persons vaccinated against smallpox.

14 Twenty-six thousand two hundred and forty-seven children treated with toxin-antitoxin mixture for immunization against diphtheria.

15 Forty-six thousand nine hundred and forty-five cows tuberculin tested, with elimination of reactors from herds, to prevent communication of bovine tuberculosis to persons through the medium of milk.

16 Two thousand three hundred and twenty-two persons treated effectively for relief from hookworm disease and for the prevention of the spread of the infection

17 Marked reduction in the spread of malaria in hundreds of localities, with an aggregate population of several hundred thousand.

18. Thirty-three thousand four hundred and fifty-one treatments to rid persons of venereal disease infection and prevent the spread of the infection.

19. Special examination of 4,333 persons for tuberculosis, of whom 1,534 were found with an active tubercular process and were advised to place themselves in the care of their private physicians and to carry out hygienic measures. Four hundred and fourteen of the positive cases were sent to institutions maintained in whole or in part for the treatment of tuberculosis.

20. Twenty-two thousand one hundred and forty cases of dangerous communicable diseases quarantined to prevent the spread of infection in the local community, the State, and throughout the country

21. The installation of 15,439 sanitary privies and 1,877 septic tanks at dwellings where previously there had been either grossly insanitary privies or no toilets of any sort.

22. Eleven thousand nine hundred and sixty-two privies repaired so as again to be of sanitary type.

23. Five thousand nine hundred and thirty-six homes connected for the first time with sanitary sewers.

[illegible] Eight [illegible] two hundred and thirty-one homes provided [illegible] water supplies in place of [illegible] contaminated water supplies

27 [illegible] of [illegible] milk supplies (the milk from [illegible] extent through the [illegible] the spread, through [illegible] and milk products [illegible] typhoid fever, scarlet fever, diphtheria, tuberculosis, septic sore throat, and infant diarrhea

28 Seven thousand six hundred and fifty-six adult persons (most of them over 40 years of age) were examined and advised about measures to conserve their health and prolong their lives

Such activities and results indicate that the plan of the work is both comprehensive and effective Considered from both a public health and an economic standpoint, the total result of such work stands in importance to our national welfare second to none other obtainable from equivalent investment of public funds

AUTOMOBILE FATALITIES, JANUARY 3 TO SEPTEMBER 11, 1926

The Department of Commerce announces that according to health officials in 78 principal cities having an aggregate estimated population of 31,878,016, there were 4,162 deaths reported from automobile accidents during the 252 days from January 3 to September 11, 1926. This is an average of over 16 deaths each day and is equivalent to an annual death rate of 18.9 per 100,000 population. Some of the deaths were due to accidents which occurred outside the corporate limits of the cities. The department has been endeavoring to have the officials make separate reports of such deaths Usually most of the deaths result from accidents occurring within the city This is especially true as regards the largest cities. Only two of the 663 deaths in New York City, and only 6 of the 435 deaths in Chicago, were caused by accidents outside the city limits. In Washington, D C, there were 52 automobile fatalities due to accidents in the city, but in addition there were 14 deaths due to accidents that occurred in the adjoining States of Maryland and Virginia On the other hand, the cities of Albany, Camden, Grand Rapids, Kansas City, Kans, Paterson, and Trenton all had more fatalities from accidents outside the city limits than from accidents within the cities.

There was considerable variation in the number of deaths from month to month. Starting with 431 in the January period, the number fell off to a minimum of 347 in March, increased to 549 for the four weeks ending June 19, was lower for the next two periods, but increased to a maximum of 560 in the period ending September 11.

The larger cities naturally show the greatest numbers of fatalities. The following table ranks 33 of the cities in ascending order accord-

ing to the mortality rate per 100,000 estimated population, due to accidents that occurred within the city limits for the first 36 weeks of this year Probably this is the fairest way of ranking the cities as regards automobile fatalities Kansas City, Kans., with an estimated population of 117,[illegible] ranks first, with one fatality and a death rate of 1.2 Indianapolis ranks thirty-third, with 59 fatalities and a death rate of 23.3

Automobile fatalities due to accidents occurring in 33 cities, January 3–September 11, 1926

City	Annual rate per 100,000 estimated population	City	Annual rate per 100,000 estimated population

EPIDEMIC OF TYPHOID FEVER CAUSED BY A "CARRIER" FOOD HANDLER

An interesting report on an epidemic of typhoid fever in Eaton Rapids, Mich., occurring in the latter part of 1925 and attributed to a typhoid bacilli carrier, is presented by Dr. George H Ramsey and Dr. C. H. Benning in the American Journal of Public Health for October

The epidemic followed a church dinner served at Eaton Rapids on November 18, 1925 Of 250 dinner guests 35 were attacked with typical and severe typhoid fever. There were 6 deaths. After a thorough investigation the outbreak was attributed to the eating of squash prepared by a typhoid carrier, whose urine and feces were found positive for typhoid bacilli, but who gave a negative Widal reaction

The history of the carrier revealed that she had suffered an attack of typhoid fever in 1900, when she was 48 years of age. Four of the five other members of the family had the disease at the same time The fifth member had had typhoid about nine years before this family outbreak. A son's wife who came to live with her mother-in-law a few years later developed typhoid fever, this being

the only case found associated with the carrier. That there were not more known cases attributed to this source is held due to the fact that all members of the family had had typhoid and that the carrier had lived in isolated residence on a farm The dinner was the first of such occasions to which she had contributed since she had left the farm and moved into Eaton Rapids

The epidemiological and laboratory evidence seems to warrant the conclusion that the source of outbreak which occurred among persons partaking of the church dinner was the squash which was prepared by the typhoid carrier.

The investigators report a mean incubation period for the epidemic of 13 days.

COMMUNITY ACTIVITIES FOR ABATEMENT OF LOCAL MOSQUITO NUISANCE

The Public Health Service received, on August 10, 1926, a letter from a resident of a small city located in a hilly section about 75 miles from Washington, D. C., asking for information about measures to abate a local mosquito nuisance, which was described as very irksome. Literature on the subject of mosquito prevention was sent and the letter was referred to Senior Sanitary Engineer J. A. Le Prince, United States Public Health Service, for suggestions about practicable, detailed procedure under the local conditions. As Mr. Le Prince's reply presents, in a plain manner, suggestions which may be useful to health officers and others concerned with mosquito prevention in many other localities, it is printed below:

NATIONAL MALARIA COMMITTEE,
Jackson, Miss, August 31, 1926

DEAR SIR: Your letter of August 9 to the Public Health Service has been referred to me for suggestions about detailed procedure under your local conditions.

You ask the old question, "What can we do?" And the answer is, "You must definitely decide that the mosquito must go" Not only you but a majority of the citizens must so decide and insist on freedom from mosquitoes If you have not already done so, you could hold a meeting of influential citizens who are particularly attractive to pestiferous mosquitoes and decide what you are going to do about it There are usually three stages of progress at such a meeting.

First. When the reception committee is particularly annoying and equally interested in the puncturing process, we say anything from "Oh my," to "D——."

Second. We swear somebody ought to do something about it

Third. We swear we are going to do something about it ourselves—and right now.

If a sufficient number of your citizens who are sick of existing conditions can be brought into the third stage, then you win

You should know what kind or kinds of mosquitoes are annoying your community. Collect some and send them in a pill box to Dr L. O. Howard, division of entomology, Department of Agriculture, Washington, D. C.

If your mosquito is *Culex* (as it probably is in your locality), then it is coming from man-made water containers that catch and hold rain water. These may be auto tires, barrels, roof gutters, or anything else that will hold rain water. The most usual place of deposit is the back yard.

Waters containing house wastes or sewage, such as small streams or natural drainage valleys, also may serve as breeding places. Learn how to locate such places. Take a tin dipper with you and dip at the grassy edges of the water and you will find the wiggle tails if they are in any natural water courses. They gather in the edges of floatage, and the richer the contamination of the water the more numerous the larvæ. There may be only one principal natural source of this sort or there may be dozens within mosquito flight range of your homes.

It is not the mosquitoes' fault, it is our fault for creating ideal breeding places for mosquito production and then cussing them for being with us.

Some mosquitoes under certain conditions live several months and females of certain species hibernate in winter season. The average life of most mosquitoes, however, is about two weeks. This is determined by noting that within about two weeks after the breeding places are eliminated mosquitoes are difficult to find. If destruction of the assumed principal source brings no results, rest assured you have missed locating the water that is producing the mosquitoes that are pestering you.

Ordinarily the pestiferous species of *Culex* travel less than a half mile; but when a sewage-carrying stream becomes stagnant so as to breed many millions of *Culex* mosquitoes, they then range out as far as a mile from the place of origin. Sewage settling basins often produce a similar condition.

It is generally a good plan to look for sewage-contaminated water when an invasion of *Culex* occurs. Follow the natural drainage valleys.

There is no practicable economical way of catching a sufficient number of the existing mosquitoes to produce relief. Elimination at the source or sources of supply is the proper procedure.

Regarding the house-yard problem, if we make Saturday mosquito day and have the mother of the family send the school children out into the back yards at 9 a. m. sharp each Saturday to look for water containers and turn them all upside down, that will settle the house-yard problem.

In Chicago last summer an inspection of the homes showed 40 per cent of the families raising their own mosquito supply. At West Point, Miss., the fire siren blows at 9 a. m. each Saturday morning, not to wake up the mosquitoes, but to wake up the kiddies who have forgotten to inspect the back yard for water containers with their mosquito larvæ.

If a quart jam jar with mosquito larvæ in 3 inches of water and the top covered with mosquito netting is placed in the school where all children can see the larvæ change into pupæ and then into mosquitoes, the children will become interested.

Also, if the children make some mosquito posters, with three prizes from the chamber of commerce for the best funny ones, you can use them in the town store windows next spring when you open your campaign. The objective is to sell the "freedom from mosquitoes" idea to the chamber of commerce and make the members think it is their idea, and to have a mosquito inspector in every family.

Twelve boy scouts can be taught in 20 minutes how to find mosquito wiggle tails in water containers. They can then inspect 300 house yards in one afternoon and inform you of the percentage of households in your community which prefer raising mosquitoes to raising flowers. Your local paper might desire to spread this news item. The boy scouts could use a few bugles in place of the fire siren on Saturday mornings next year, and the local papers could explain what all the row is about.

The time to eliminate the 1927 mosquito crop is when school opens in September, 1926.

Waste oil from the garages, thinned with a little kerosene, used as a thin film on puddles in stream heads, and on other prolific sources of mosquitoes three or four times a month will stop mosquito production. Apply the film of oil only where larvæ are present.

You must expect plenty of adverse criticism when operations are started, but this criticism will die a natural death, and the knockers will then tell you "We did it"—after you have freedom from mosquitoes.

Sincerely yours, J. A. LePrince.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Water Purification for Small Cities. H. V. Pedersen, sanitary engineer, State Board of Health, Des Moines, Iowa. *Journal American Water Works Association*, vol. 15, No. 5, May, 1926, pp. 549–553. (Abstract by Sol Pincus.)

The reluctance of the small city to give consideration to the development of a surface water supply with purification, after the earlier shallow-well stage is outgrown, is presented in this paper. A predilection to ground water supplies is generally shown by the council of the small cities, due largely to the fear of the high cost of operation and expert attention required for the purification plant. The author presents cases where far more satisfactory supplies of greater sanitary safety and soft quality were obtained by using a surface source and filtration plant. In one example cited the total cost of filtration plant and chlorinator for a city of 1,500 population was $11,000.

The author holds that competent operators for the small water-purification plant can generally be readily developed locally if the city will only provide a fair salary.

History of a Typhoid Carrier. Anon. *Public Health News*, vol. 11, Nos. 5 and 6, April–May, 1926, pp. 143–144. (Abstract by W. W. White.)

The history of a man is given who was known to be a carrier of typhoid fever at Cranbury, N. J. Forty cases and three deaths in which milk was found to be the vector of infection were first reported in August, 1915. In March and April of the same year, 20 cases occurred among users of milk from the dairy where this man was employed.

In 1916 this typhoid carrier was found working on a farm near Princeton Junction, where an investigation was made regarding an outbreak of typhoid. His discovery led to his again losing his job. In 1917 an epidemic of 13 cases at Bordentown was caused by the same carrier, after which he disappeared until 1921. Unable to get work on account of his reputation, he was given a position with the New Jersey State Laboratory. He died February 22, 1926. His history showed that he had typhoid in 1884. The number of cases he caused before 1915 is unknown. Since that time he is known to have been the source of infection of 77 cases with 4 deaths.

Malaria in New England. M. J. Quinn. *Boston Medical and Surgical Journal,* vol 194, 1926, pp 244–247 (18 refs) (Abstract by J F C H.) From *Bulletin of Hygiene,* vol. 1, No 7, July, 1926, p 563

"A survey of malaria in New England from 1634 to the present day The disease is still endemic in southern New England and probably more common generally than available statistics indicate. It is probable that *Anopheles* can be found in this State at all levels below 2,000 feet "

Observations on the Emergence of Anopheles Mosquitoes. G. H. Bradley. *The American Journal of Tropical Medicine,* vol 6, No. 4, July, 1926, pp 283–298 (Abstract by L D Fricks)

The author here reports a series of observations conducted during the years 1921, 1922, and 1924, around Mound, La , on the rate of emergence of *Anopheles* per unit of area in selected breeding places, and also compares these rates with similar observations of *Anopheles* emergence as reported from other parts of the world.

Nets of known size were placed over the selected water surfaces and daily collections of adults found inside the nets were made. A total of 904 9 square yards of water surface was covered by nets, and 585 *Anopheles* were collected, giving an average daily emergence of 0 653 per square yard An increase in the number of larvae present in selected areas did not cause a proportionate increase in the rate of emergence. This may have resulted from scarcity of food or activity of larvae enemies Of the *Anopheles* which emerged, females were somewhat greater in numbers than males; 516 females to 461 males in the total catch

Examination for Entrance into the Regular Corps of the Public Health Service

Examinations of candidates for entrance into the Regular Corps of the United States Public Health Service will be held at the following-named places on the dates specified·

Washington, D C	Dec. 6, 1926.
Chicago, Ill	Dec 6, 1926.
New Orleans, La	Dec. 6, 1926.
San Francisco, Calif	Dec 6, 1926.

Candidates must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily oral, written, and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President, with the advice and consent of the Senate

Requests for information or permission to take this examination should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

DEATHS DURING WEEK ENDED OCTOBER 9, 1926

Summary of information received by telegraph from industrial insurance companies for week ended October 9, 1926, and corresponding week of 1925. (From the Weekly Health Index, October 13, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 64 cities.
[4] Deaths for week ended Friday, October 8, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta 31, Baltimore 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Kansas City, Kans., 14, Louisville 17, Memphis 38, Nashville 30, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary, and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended October 16, 1926

Massachusetts	11	209	30	3	70	2	59	353	0	51
New Jersey	3	173	3	2	36		12	174	0	138
North Dakota		6			24		3	104	16	14
Tennessee	2	140	43	376	25	25	8	130	7	881
Wisconsin	4	117	55		381		8	198	19	43

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended October 2, 1926, 38 States reported 1,421 cases of diphtheria. For the week ended October 3, 1925, the same States reported 1,426 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,350,000, reported 744 cases of diphtheria for the week ended October 2, 1926. Last year for the corresponding week they reported 661 cases. The estimated expectancy for these cities was 912 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles—Thirty-seven States reported 856 cases of measles for the week ended October 2, 1926, and 433 cases of this disease for the week ended October 3, 1925. One hundred cities reported 212 cases of measles for the week this year, and 224 cases last year

Poliomyelitis.—The health officers of 37 States reported 79 cases of poliomyelitis for the week ended October 2, 1926. The same States reported 282 cases for the week ended October 3, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 1,533 cases; last year, 1,174 cases; 100 cities—this year, 584 cases, last year, 493 cases; estimated expectancy, 492 cases.

Smallpox.—For the week ended October 2, 1926, 38 States reported 70 cases of smallpox. Last year for the corresponding week they reported 70 cases. One hundred cities reported smallpox for the week as follows: 1926, 6 cases; 1925, 11 cases, estimated expectancy, 17 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—One thousand one hundred and eighty-three cases of typhoid fever were reported for the week ended October 2, 1926, by 38 States. For the corresponding week of 1925, the same States reported 1,132 cases of this disease. One hundred cities reported 246 cases of typhoid fever for the week this year and 222 cases for the corresponding week last year. The estimated expectancy for these cities was 218 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,690,000, as follows: 1926, 427 deaths; 1925, 367 deaths.

City reports for week ended October 2, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended October 2, 1926, compared with those for a like period ended October 3, 1925 The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, August 29 to October 2, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Hawaii—Honolulu

Society Islands—Papeete

AFRICA

Egypt—Port Said, Suez, Alexandria.

Anglo-Egyptian Sudan—Port Sudan, Suakin.

Eritrea—Massaua

French Somaliland—Jibuti.

British Somaliland.—Berbera.

Italian Somaliland.—Mogadiscio.

Kenya—Mombasa.

Zanzibar—Zanzibar.

Tanganyika.—Dar-es-Salaam

Seychelles—Victoria.

Mauritius—Port Louis

Portuguese East Africa—Mozambique, Beira, Lourenço-Marques.

Union of South Africa—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indies—Samarinda, Pontianak, Menado.

Madagascar.—Tamatave, Majunga.

BRAZIL

Plague—Paranagua—October 8, 1926.—Information was received under date of October 8, 1926, of the presence of plague at the port of Paranagua, State of Paraná, Brazil.

CHILE

Mortality—Concepcion—July, 1926.—During the month of July, 1926, 176 deaths from all causes were reported at Concepcion, Chile (population, 64,780) Of these, 64 deaths were in children under 1 year of age. Causes of deaths were reported as follows: Bronchopneumonia, 11, diseases of the heart, 11; dysentery, 1; influenza, 1; meningitis, 7, pneumonia, 25; tuberculosis, 30 Mortality from pneumonia, tuberculosis, and diseases of the respiratory system generally was stated to have been above the average, due to excessive rainfall and damp, cold weather

CUBA

Communicable diseases—Habana—August and September, 1926.—During the months of August and September, 1926, communicable diseases were reported at Habana, Cuba, as follows.

August

Disease	New cases	Deaths	Remaining under treatment Aug 31, 1926	Disease	New cases	Deaths	Remaining under treatment Aug 31, 1926
Chicken pox	3		2	Measles	14		15
Diphtheria	9		1	Paratyphoid fever	4		1
Leprosy			9	Scarlet fever	7		4
Malaria [1]	114	2	40	Typhoid fever [1]	44	7	38

September

Disease	New cases	Deaths	Remaining under treatment Sept 30, 1926	Disease	New cases	Deaths	Remaining under treatment Sept 30, 1926

Leprosy	1	1	9	Scarlet fever	10		3
Malaria [1]	61	1	19	Typhoid fever [1]	52	10	45

[1] Many of these cases from the interior

EGYPT

Plague—September 3–9, 1926.—During the week ended September 9, 1926, 12 cases of plague were reported in Egypt. The cases occurred in the district of Sidi Barani, in the western desert province.

Summary—January 1–September 9, 1926.—During the period from January 1 to September 9, 1926, 128 cases of plague were reported in Egypt, as compared with 111 cases reported for the corresponding period of the year 1925.

JAMAICA

Smallpox (alastrim)—Other communicable diseases—August 29–September 25, 1926.—During the period August 29 to September 25, 1926, 60 cases of smallpox (reported as alastrim) were reported in localities other than Kingston in the island of Jamaica. Other communicable diseases were reported as follows.

Disease	Kingston	Other localities	Disease	Kingston	Other localities
Chicken pox		2	Puerperal infection		1
Measles	2	13	Tuberculosis (pulmonary)	11	38
Ophthalmia neonatorum		2	Typhoid fever	13	112

MEXICO

Typhoid fever—Progreso—October 2, 1926.—During the week ended October 2, 1926, one death from typhoid fever was reported at Progreso, Mexico, with 40 cases reported present.

Water supply.—Progreso was stated to have no rainfall and no running water; also no wells of potable water, all wells being saline. The water supply is from cisterns. At the close of the summer season many of these cisterns are left locked by their owners and the water in them becomes stagnant.

SAMOA

Further relative to epidemic influenza—August, 1926.—Under date of August 21, 1926, epidemic influenza was reported present in a mild but highly infectious form at Apia, Samoa, and vicinity, with extension of infected area along the coast and an estimated number of 200 cases with no mortality.[1]

Later estimates place the number of reported cases at from 500 to 1,000, with an extension of infected area.

Influenza in American Samoa.—Further information shows the appearance of epidemic influenza in American Samoa, at first within a restricted area but later rapidly spreading. On August 19, 800 cases were reported present with one death from pneumonia (pneumococcus).

Measles.[1]—Measles was reported present in American Samoa, August 20, at two points. To August 18, 21 cases were reported present; in western Samoa, August 19, 14 cases.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg. Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests

VOL. 41 OCTOBER 29, 1926 NO. 44

ENDEMIC GOITER AND SCHOOL ABSENTEEISM

By ROBERT OLESEN, Surgeon, and NEIL E TAYLOR, Acting Assistant Surgeon, United States Public Health Service

INTRODUCTION

Many writers have asserted without qualification that endemic goiter as it is encountered in the United States exerts a distinctly deleterious influence upon the minds and bodies of children If this statement is true it should be possible to detect some of the injurious effects by various observations among school children Several investigations of this nature have been completed, the results being available in publications of the United States Public Health Service.[1]

Additional information concerning the probable relationship between thyroid status and certain physical conditions among children can undoubtedly be obtained by noting absenteeism in schools The amount and character of the time lost by children from school are the points on which the present study hinges. If children are adversely affected by enlarged thyroid glands the result may, in some tangible way, be reflected in the school attendance

Limitations of the present study.—The conclusions which may be drawn from the investigation herein detailed are manifestly limited. The prevalence of endemic thyroid enlargement in Cincinnati is comparatively moderate in character. The inclusion of a relatively small number of sixth-grade school children and also younger children in open-air classes for study purposes likewise limits the possible findings to a small group Therefore, the results of the present investigation should be regarded as specific rather than general. Furthermore, the results of the present suggestive inquiry in Cincinnati may differ radically from more intensive studies made in other sections having a high prevalence of simple goiter. Investigations of somewhat similar trend among larger numbers of older children in areas having a high incidence of simple goiter might materially alter the results of the study here presented.

Purpose and scope of the investigation.—The present study was undertaken for the purpose of learning the differences, if any, in school attendance of children with and those without thyroid enlargement. Attendance records were kept of 479 white boys and 478 white girls in one grade, the sixth. These children, ranging in age from 9 to 16 years, attended nine schools located in different parts of the city. By this process of selection a cross section of economic status and environmental conditions was afforded. Eighty-three colored boys and 107 colored girls, most of whom were attending the sixth grade of two schools, were likewise observed. In order to ascertain and compare the relative frequency of respiratory affections in dissimilar groups, the attendance of 23 white boys and 18 colored boys, in addition to 35 white girls and 25 colored girls in open-air classes of the lower grades, was also noted. These children were between 7 and 13 years of age.

The individuals included in the present investigation represent new material, the observations not having previously been utilized in any of the studies made in Cincinnati. Needless to say such a study could not have been undertaken without the sympathetic and generous assistance of school principals, teachers, and nurses. The writers are, therefore, under many obligations to the local school and health authorities for helpful suggestions and practical aid in securing the requisite data.

Methods.—In pursuing the study of absenteeism among Cincinnati school children liberal use was made of the methods employed by Dr. Louise Taylor-Jones in an investigation made in Washington, D. C., during the 1923–24 school session.[2]

The object of the study was made known to the teachers and nurses by verbal and written explanation. Very little was said to the children themselves lest disturbing factors should be projected into the inquiry. The extent and cause of each individual absence was recorded by the teacher upon the return of the absentee. Thereupon the school nurse investigated the cause of the absence and insured its approximate accuracy. Once a week the separate records were checked by the writers and the data transferred to individual cards, one of which, containing all data for the entire school year, was available for each pupil. The records were secured from December 1, 1924, to June 19, 1925, the close of the school year.

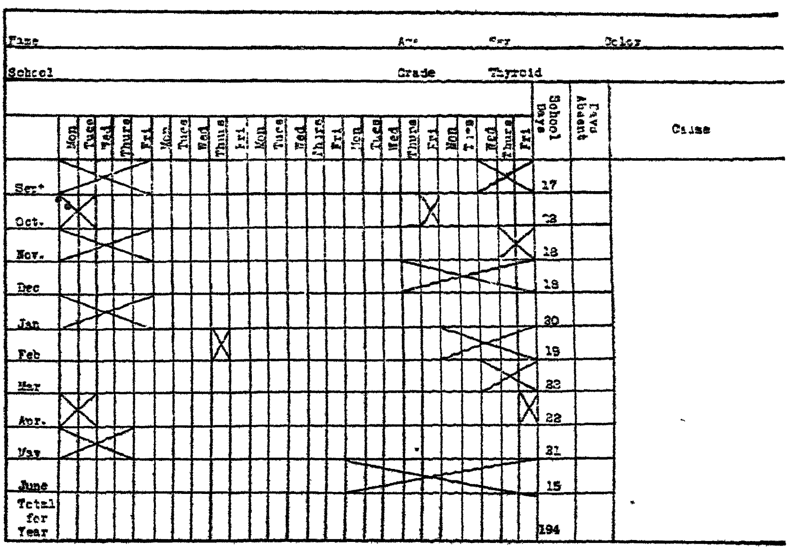
In the main the classification of causes of absence suggested by Doctor Taylor-Jones was followed in the present study. The several headings under which causes of absence were recorded are as follows:

1. Influenza and common colds.
2. Illnesses other than colds.

[2] Louise Taylor-Jones: Causes of Absence in One Grade of 15 Public Schools in Washington, D. C. Pub. Health Rep., vol. 39, No. 37, Sept. 12, 1924. (Reprint No. 954.)

3. Quarantine because of personal illness or illness of other members of family.
4. Bad weather.
5. Truancy
6. Religious holidays.
7. Miscellaneous causes, principally of a preventable character.

In recording the duration and causes of absence a revised form, based upon the original described by Doctor Taylor-Jones, was utilized. By omitting Saturdays and Sundays waste space was decreased. In brief, the form used in Cincinnati made use of the shorter school calendar instead of the regular calendar. The revised record sheet is shown as Form 1



FORM 1.—United States Public Health Service thyroid-absenteeism study

RESULTS

While the present study had for its primary object the determination of the amount and cause of absence among thyroid-normal and thyroid-enlarged children, certain interesting collateral information likewise became available. Many points of interest to health officials and school authorities are contained in the data secured, but only the more pertinent information relating to thyroid status has been included in the present paper.

Thyroid enlargement.—The numbers of each degree of thyroid enlargement found among the sixth-grade children are shown in Table 1. Thyroid enlargements were present among 55.5 per cent of the white girls and 65.4 per cent of the colored girls examined. Forty-two and nine-tenths per cent of the white boys and 50.6 per cent of the colored boys also had thyroid enlargement. The percentages of

thyroid enlargements among the children of the open-air classes, shown in Table 2, were lower, the individuals of this group being younger.

Total and average time losses.—The total number of days lost from school by the white boys and girls attending the sixth grade and the general causes of the absence are shown in Table 3. Similar information for the colored children is available in Table 4. It will be noted that 2,953 days were missed by the 479 white boys and 3,253 days by the 478 white girls There was an average loss of 6.1 days among the boys and 6 8 days among the girls. The average absenteeism among the colored children was much higher, being 11.8 days for the colored boys and 10 3 days for the colored girls. Considering that the records do not cover the entire school year, the average absence chargeable to each pupil is considerable

TABLE 3.—*Total and average number of days of absence from school during the 1924–25 session among 479 white boys and 478 white girls in the sixth grade of the Cincinnati public schools, according to cause of absence, and presence or absence of thyroid enlargement*

Absence in relation to thyroid status.—Coming to a consideration of the differences in absenteeism between thyroid-normal and thyroid-enlarged children it is apparent that less time was lost by those of the latter group. The differences, however, are neither marked nor significant. Average absences from specific causes were, with few exceptions, slightly less among the thyroid-enlarged children. The similarity in the types and durations of absences from various causes is shown in Chart 1. In preparing the graphic representations presented in this chart, the losses from common colds, other sicknesses, and quarantine because of personal illness or illness of other members of family, have been combined. An examination of Chart 1 shows that the average monthly loss of time from school was slightly less among the children who had no enlargement of the thyroid gland. Absence from school on account of causes associated with illness was most marked during the month of March and was more conspicuous among the girls.

Combined time losses from bad weather, truancy, and religious holidays were about equally distributed between the thyroid-enlarged and thyroid-normal individuals, the distribution being irregular and indistinct.

The miscellaneous causes of school absence, largely avoidable in character, show similar trends, which reach their maxima in April. The differences in school absence between those with and those without thyroid involvement are not clearly marked and therefore lack significance

Absence because of common colds was slightly more frequent among the girls. Loss of school time because of personal quarantine or the illness of other members of the family was slightly more frequent among the thyroid-normal children, both white and colored. Truancy appears to be a relatively unimportant cause of absence

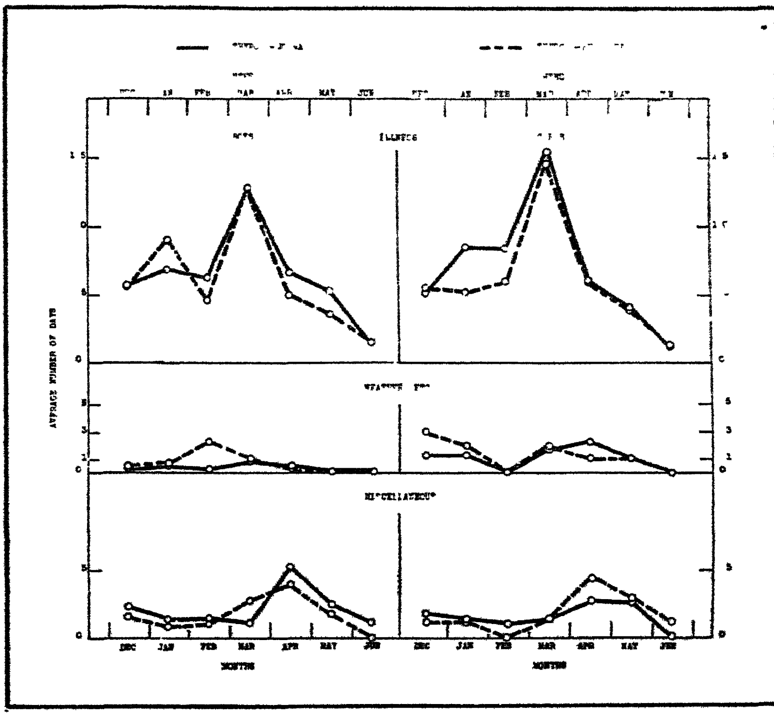

CHART 1 —Average number of days lost from school on account of illness, bad weather, and miscellaneous causes by thyroid-normal and thyroid-enlarged boys and girls in Cincinnati

among the children observed, though more frequent among the colored children than among the white and among both the white and colored boys than among the girls.

Records from open-air classes.—The records of absence among those attending open-air classes are open to the just criticism that relatively few observations are available, and these among younger children. Despite this obvious deficiency it is apparent, after examining Tables 5 and 6, that there are numerous points of comparative interest. Foremost in interest is the fact that the total average absence in the open-air classes exceeds the days lost by

children in the regular classes Furthermore, except among the colored boys, average absence from common colds is greater among the children of the open-air classes.

TABLE 5—*Total and average number of days of absence from school, during the 1924–25 session, among 23 white boys and 35 white girls in the open-air classes of the Cincinnati public schools, according to cause of absence, and presence or absence of thyroid enlargement*

Further study of Tables 5 and 6 shows that a greater average number of days was lost by the thyroid-enlarged white boys and colored girls than by those with normal thyroids. Among the white girls and colored boys the average losses from absenteeism were greater among the thyroid-normal individuals. In all probability the number of observations available among the children of the open-air classes was too small to permit of drawing conclusions relative to the influence of thyroid condition.

SUMMARY

1. An investigation was undertaken in Cincinnati for the purpose of learning the character and extent of absence from school among thyroid-normal and thyroid-enlarged children.

2. Records were kept of absences among 479 white and 83 colored boys and 478 white and 107 colored girls in the sixth grade of 11 schools. In addition, 23 white and 18 colored boys and 35 white and colored girls attending open-air classes were also studied.

3. Thyroid enlargements were present among 55.5 per cent of the white girls and 65.4 of the colored girls examined. Forty-two and nine-tenths per cent of the white boys and 50.6 per cent of the colored boys had thyroid enlargement. Lower percentages of thyroid involvements were found among the children attending the open-air classes, who were younger.

4. Average absences from school were much greater among the colored than among the white children. Among the white children the average absences were slightly greater among the girls. The opposite condition held among the colored children.

5. A comparison of thyroid-normal and thyroid-enlarged children shows, in the particular group under consideration, a slightly greater average absence in the former group. Common colds caused a slightly greater average loss of time from school among the girls.

6 The average time loss of pupils in the open-air classes exceeded the average absence of those attending the regular classes Except among the colored boys, the average absence because of common colds was greater among those attending the open-air classes Absenteeism among the thyroid-normal and thyroid-enlarged children in the open-air classes was irregular in character and without significance, probably because of the small numbers, the lower ages, and relatively small amount of thyroid involvement

DISCUSSION

The observations which have been made in the present article apply, of course, to a limited group in a single community. Whether the extension of a similar study to a large group of older children would alter the findings is problematical Certainly it would be essential, before concluding that thyroid enlargement exerts no influence upon school attendance, to conduct investigations in other parts of the country, particularly in districts of relatively higher goiter incidence.

As a means of contributing to the knowledge concerning the ill effects of endemic goiter, a record of school attendance holds forth considerable promise. In the investigation described in the present paper it has been demonstrated that the average school attendance, at least in a selected group, was slightly, though not significantly, better among the individuals with some degree of enlargement of the thyroid gland It follows, therefore, that the various mental and physical ailments from which children with endemic goiter are alleged to suffer, were not measurably reflected in the school attendance of the particular group under observation.

WHAT THE GOVERNMENT IS DOING FOR TUBERCULOUS PERSONS[1]

By Lucy Minnigerode, Superintendent of Nurses, United States Public Health Service

The subject "What the Government is doing for tuberculous persons" touches some interesting phases of Government work

Many persons are no doubt familiar with the fact that there are several departments and bureaus of the Government engaged in medical work either directly or indirectly. Following are the most important of these branches of the Federal Government directly concerned with medical activities: The Army; the Navy, the Veterans' Bureau; the Public Health Service; the Children's Bureau, of the Department of Labor, which administers the Sheppard-Towner Act; the Office of Indian Affairs, of the Interior Department, which

[1] Read at the Seventh Annual Camp of Instruction, held under the auspices of the Pennsylvania State Department of Health, at Mont Alto Sanatorium June 22, 1926

is responsible for the medical care and treatment of the Indians on Government reservations, the Bureau of Education, of the same department, which is charged with providing medical relief for the natives of Alaska; the Bureau of Animal Industry and the Bureau of Home Economics, of the Department of Agriculture, and the United States Employees' Compensation Commission.

The material presented here relating to the various departments has been secured in each instance from the department concerned in order to insure accuracy. In requesting statements from these various Federal departments and offices, those which were not dealing directly with tuberculosis were not included.

Medical Department of the Army

1 PREVENTION

Under "prevention" are included annual physical examinations of officers and nurses, improvement of housing and personal hygiene, the proper and efficient treatment of respiratory and contagious diseases, thus preventing recrudescence of quiescent lesions, establishment of a special department of nutrition under an expert physiologist, compulsory courses for internes and general medical officers at Fitzsimons General Hospital (the tuberculosis hospital of the Army), courses for nurses, including affiliating student nurses from Denver hospitals, at the Fitzsimons General Hospital, and the employment of a public health nurse, a member of the Army Nurse Corps, at one large Army camp, Fort Benning, Ga., whose visiting nurse-activities include examination of school children of the post and all forms of child welfare.

Most tuberculosis in the Army comes in from civil life. The amount found depends upon the efficiency of physical examinations—on admission and afterwards During recruiting for the war, local examining boards culled out 69,935 cases of tuberculosis, including suspected cases, out of a total of approximately 3,700,000 men. In addition to this number, Army camp boards turned back approximately 15,000 men. During the war 22,812 men, including volunteers as well as selected service men, were discharged on account of tuberculosis

The Army had an especially organized tuberculosis service with a branch in each camp during the war. The duty of the officers in these services was to eliminate and treat cases of tuberculosis. Through this service comparatively few cases of tuberculosis got into the Expeditionary Forces. For example, the case rate of tuberculosis in the Army in the United States during the war was 13.15 per thousand per annum, and in the American Expeditionary Forces was 4.29, which shows that practically three times as many tuberculosis cases were found and eliminated in the camps of the United States as were in the American Expeditionary Forces.

2. TREATMENT DURING THE WAR

The Army conducted four large hospitals for tuberculosis, located at the following-named places: Oteen, N C, Fort Bayard, N. Mex., Whipple Barracks, Ariz, and Denver, Colo. These hospitals cared for 38,607 patients, of whom 2,766 died. Many of these patients continued their treatment in the Veterans' Bureau and other hospitals At the present time the Army has one hospital for tuberculosis, Fitzsimons, a large general hospital at Denver, Colo. Its normal capacity is 1,847 beds. During the past year it has had 4,000 admissions, approximately all for tuberculosis or suspected tuberculosis All military sick of this class are sent to Fitzsimons Hospital, where the latest methods in the care of tuberculosis are employed Excellent results have been accomplished by heliotherapy and surgery. The Army also cares for certain tuberculosis patients of the Veterans' Bureau at the Army hospitals at El Paso and San Antonio, Tex.

The Public Health Service

The Public Health Service publishes weekly reports showing the prevalence of disease, including tuberculosis. It also publishes popular and technical articles dealing with health and sanitation. I have here a number of pamphlets on tuberculosis which are available upon request from the Public Health Service. Studies dealing either directly or indirectly with the problems of tuberculosis are constantly being made. Among the publications is the report of an investigation concerning tuberculosis in Porto Rico made by Doctor Townsend, of the Public Health Service, and published in 1923. There is being conducted at the present time a study of the distribution and prevalence of all respiratory diseases, which was begun about three years ago. Student groups in 13 of the leading universities of the United States were selected for this investigation, as well as families of medical officers of the Army, Navy, and Public Health Service, and faculty members of the above-mentioned universities. Selection of universities was made so as to include different areas of the United States. Final results of this investigation have not yet been published, but, when the study is completed, we shall no doubt have some new valuable information on the subject. There are also being conducted extensive studies on the effect of sunlight on health and disease. Some of the results of these studies will be published in connection with the report on the prevalence of respiratory diseases. It is believed that these studies will have a bearing on the whole problem of tuberculosis. Statistics of all kinds are available through the morbidity studies conducted by the Public Health Service.

The Public Health Service has been conducting several studies on the relation of dust to the health of industrial workers. One of the

principal objects of these studies is to determine as accurately as possible whether or not a specific dust hazard has any effect as a predisposing cause of reactivation of tubercle. The particular dusts included are those prevailing in cement, silver polishing, anthracite, bituminous and granite industries, as well as certain industries in which organic dusts prevail The studies themselves are extremely intensive in character, involving a careful history of each individual observed, a physical examination, X ray of all suspicious cases, at least two years of continuous observation with regard to respiratory as well as other illnesses, and a thorough study of the occupations from the point of view of the dust hazard, its severity as well as the chemical composition of the dust

As a part of the statistical research work, statistics of tuberculosis prevalence are being collected gradually for different groups of individuals, including industrial employees, children of school age, and general population groups, living and working under different conditions. The purpose of this collection of data is to obtain a sufficient amount of dependable information on the incidence of tuberculosis and the conditions under which the disease is most prevalent. In addition to the morbidity statistics, a study has been in progress for some time on certain phases of mortality from tuberculosis, with the particular purpose of trying to discover some of the general conditions which appear to be related to the wide differences in mortality from the disease in different localities, geographic areas, race stock, varying industrial conditions, etc.

Since 1906, under an Executive order, the Public Health Service has made physical examinations of persons employed by the Government who are believed to have tuberculosis (or other communicable diseases), making a true report to the official concerned. You will note that this order originated at a time when more importance was placed upon the possibility of infection of adults from fellow employees than now. It operates now to assist in the early diagnosis of tuberculosis.

Officers of the Public Health Service make physical examinations of civil service applicants and employees. Approximately 19,000 such examinations are made annually. Tuberculosis or conditions predisposing thereto are sometimes detected.

The service operates a hospital for the care of tuberculous merchant seamen and other beneficiaries at Fort Stanton, N. Mex., where approximately 230 patients are constantly under treatment.

Patients are not sent to Fort Stanton except after careful scrutiny of the clinical histories in order to prevent unwise transfers. (See Hospital Division Circular No. 218, of July 12, 1922.) It is, however, I think, creditable to the Public Health Service that of the large number of tuberculous patients transferred to Fort Stanton, 1,228

have died there since 1898. This speaks very well for the place, since it is able to persuade men who, of course, could leave the place at their discretion, to remain there until they die, thus preventing the infection of others, particularly young children, with whom they might come in contact in sailors' boarding houses or in their own homes

However, it is not only at Fort Stanton that tuberculous patients are cared for Every hospital in the Public Health Service has beds available for the care of the tuberculosis patient. This is a definite policy of the service, which, for a number of years, has strongly advocated the inclusion of wards for tuberculous persons in all civilian, municipal, or Government hospitals The advisability of tuberculosis wards in general hospitals is preached by the Public Health Service whenever opportunity is presented, and I take pleasure in again urging that every effort be made toward the accomplishment of this purpose by all agencies interested in the care of the tuberculous patient.

United States Veterans' Bureau

The United States Veterans' Bureau has 18 hospitals caring for over 5,000 tuberculous patients who are beneficiaries of the Veterans' Bureau. In addition to this, in 52 regional offices there are nurses on duty caring for beneficiaries under the direction of medical officers, the purpose being to educate as well as care for these patients The latest consolidated report of these activities shows 16,434 tuberculosis cases under supervision in these 52 regional offices Each nurse has a given territory assigned to her and is responsible for the supervision of all beneficiaries, and provision for their needs, in that area Beneficiaries with a diagnosis of tuberculosis are visited as often as it is deemed necessary by the medical officer in charge of the case. Instruction is given regarding daily rest hour, care of dishes and linen, disposal of sputum, the caution necessary to protect others from infection, especially children, recreation, exercise, etc

Before a beneficiary is discharged from one of the hospitals a formal notice is sent to the regional office requesting an investigation of the home conditions. The nurse is directed to make investigation, and she forwards her report through proper channels to the hospital requesting the information After the report is made to the medical officer in charge of the hospital, and provided the home conditions are approved, the beneficiary is allowed to take home treatment under supervision Following his return to his home, the nurse takes up the supervision of the case and the claimant then reports, if able to do so, to the clinic for the purpose of treatment and periodical reexamination. If home conditions are not suitable, they are disapproved and the family is instructed as to the changes which may be necessary.

Since 1923 an intensive program of supervision and education has been outlined in many of the regional offices to be carried on with tuberculous beneficiaries. The idea of this group instruction is for the purpose of bringing patient and physician in closer touch, so that the nurse might have the support that could come only from the fact that there is a physician in charge of the case The following requirements for entrance into these classes of instruction were established:

1 Patient is required to have at least one year of hospital treatment with instruction in regard to his own case while in the hospital

2 Home conditions must meet the requirements of the United States Veterans' Bureau

3 The patient must promise to cooperate fully with the doctor and the nurse.

4 Out-patient treatment must have been authorized, hospitalization not recommended, and the patient is such as the examining specialist feels would benefit by this instruction

For instance, the patient who had not had sufficient hospitalization to be admitted into the class was urged to accept further hospital treatment. Those patients whose homes did not meet the requirements of the regulations of the Veterans' Bureau were encouraged to move into more suitable quarters

A comprehensive course of instruction is given to patients during their period of hospitalization Upon admission to the hospital the patient is instructed as to the importance of following faithfully all rules and regulations He is made to understand that such rules are made to insure his proper treatment and speedy recovery and are not merely matters of discipline This teaching, initiated in the receiving ward, is followed up by the ward surgeon, who, in addition, explains to the patient in lay language enough of the pathology of his case to secure his cooperation in treatment. A personal interest is shown in the welfare of the individual patient and confidence is established between him and the physician. Upon discharge from the hospital, the patient is acquainted with his limitations as regards work, exercise, etc.

All tuberculosis hospitals of the Veterans' Bureau have instituted courses of instructions for the nurses on duty In many instances in which the hospital and regional office are located in the same city, arrangements have been made for the nurses to attend the staff meetings and courses of study in the hospital Several offices have adopted a plan whereby a specialist in tuberculosis devotes a short period of time, preferably at the beginning of the day, to instruction in proper procedure relative to follow-up nursing of beneficiaries and their families.

Postgraduate courses, or rather courses of intensive instruction, in tuberculosis for both physicians and nurses have been held in United States Veterans' Hospital No. 60, Oteen, N. C , and in United States

Veterans' Hospital No. 41, New Haven, Conn. Acknowledged leaders in tuberculosis work participated. These courses have attained a degree of success not equaled in this country.

In some of the hospitals, model wards have been established and every effort is made to accomplish the essential purpose of hospitalization, and the information the patient receives in intramural surroundings helps to keep him from having a recurrence of his trouble It also assists him in teaching his family to live correctly after he goes home

A bulletin on tuberculosis nursing for the guidance of nurses has also been prepared in the Nursing Service of the Veterans' Bureau. This bulletin, known as General Order No 343, outlines the function of the follow-up nurses in the Veterans' Bureau in their visits to bureau beneficiaries who are not receiving treatment in hospitals and who are actually in need of follow-up nursing care

From the report of these activities it will be seen that two or possibly three activities in regard to tuberculosis are being carried on by the Veterans' Bureau. The first of these is treatment of actual cases of tuberculosis in hospitals established for that purpose The second is the follow-up of tuberculous patients who have become inactive and allowed to return to their homes, and keeping under supervision all these patients so that they may not become again reactivated The third is the educational and preventive work, which is by far the most important in its bearing upon the whole tuberculosis problem throughout the country A tremendous amount of work is being done in the Veterans' Bureau toward the education of the patient in regard to the infectiousness of his disease, the menace which he may be to members of his family through carelessness, impressing upon him particularly that he may be a menace to his children. His family is instructed in the measures which are necessary for keeping the patient well and for preventing conveyance of the infection to others.

Physicians and nurses are trained through these educational activities in the proper care of tuberculous patients At the close of the war, when the ex-service men were being discharged by the thousands, it was almost impossible to secure either physicians or nurses adequately trained in the proper care of tuberculous patients. It was for this reason that the Public Health Service instituted the first school in tuberculosis treatment, which was held at Oteen, N. C., mention of which has already been made. The Veterans' Bureau, realizing the value of this school, has continued to "carry on" and has developed an educational program in the care of tuberculous patients which can not fail to be of great benefit to the country at large by increasing the number of medical personnel trained in the care of tuberculosis.

Office of Indian Affairs

For the purpose of treating tuberculous patients, there are maintained in the Indian Service six sanatoria schools, with a combined capacity of 464 beds, and six sanatoria hospitals, with a bed capacity of 124 In addition to these a number of the general hospitals have facilities for accommodating a limited number of Indians afflicted with tuberculosis

The tuberculosis sanatoria are intended for the care and treatment of Indians where the process is so active and advanced that the chances of permanent arrest are remote

The sanatoria schools are operated for the purpose of treating incipient cases of tuberculosis among children of school age, and a modified course of education is provided for the patients in addition to their treatment for tuberculosis As a rule, open-air schoolrooms are provided for these institutions

Besides those for whom institutional treatment has been provided, a large number of tuberculous patients are being treated daily in their homes by agency physicians, assisted by the field nurses and field matrons This class of patients is increasing rapidly as the Indian is fast becoming aware of the fact that his medicine man has nothing to offer that is effective in the treatment of tuberculosis, and his own observations are beginning to reveal to his mind that there are advantages to be gained by pursuing the white doctor's course, looking toward the eradication of the worst enemy to his health

The capacity of the institutions for the care of tuberculous patients is not nearly sufficient to take care of those who are now making application for this class of treatment.

Employees' Compensation Commission

Ever since its inception the Employees' Compensation Commission has held that pulmonary tuberculosis may, under certain conditions, be considered an occupational disease This consideration is entirely apart from the occurrence of tuberculosis following accidental injuries, and is a field in which most State and foreign compensation commissions have made little progress so far. As pulmonary tuberculosis is such a common disease, it has been necessary for the commission to differentiate between the ordinary cases of sickness and those which may fairly be ascribed directly to occupation. While the latter class of cases is comparatively rare, the commission has always felt that in equity a case of clearly occupational tuberculosis should receive the benefits of the compensation act. The experience of the commission, however, has demonstrated clearly that such claims should not receive favorable consideration

until a careful investigation and survey have been made by an especially trained investigator The consensus of medical opinion now is that contact is a relatively unimportant consideration in the etiology of adult tuberculosis On the other hand, occupations showing special hardships which would materially decrease the resistance of the individual, thus allowing the activation of a latent tuberculous process, by reason of extreme overwork, unusual climatic exposure, or various occupational hazards, such as dust, form the basis for the allowance of such cases as can be given favorable consideration.

Bureau of Animal Industry

The Bureau of Animal Industry is active in developing accredited herds—that is, tuberculosis-free herds—and in general eradication of tuberculosis among cattle

SANITATION OF TOURIST CAMPS

With the phenomenal increase in the number of passenger automobiles throughout the United States, and the increasing tendency for families to take long trips during vacation times, thousands of tourist camps have been established for the accommodation of many of these tourists who do not stop at hotels A new sanitary problem has thus arisen, and many States have already adopted regulations for the sanitary control of these camps.

In a recent report to the State board of health, the State supervisor of tourist camps and swimming pools of Texas states that during the summer months he inspected 225 camps and 27 swimming pools in 78 different counties of the State, and also 15 private camps and camps used by organizations. Approval was given only to those camps complying with the regulations of the State board of health, which are, constant and adequate supervision by a full-time caretaker, a safe and protected water supply, approved method of sewage disposal, and a safe and adequate method of garbage disposal.

The report also states:

"A noticeable feature is the diminution of free tourist camps in the State. Most municipalities have awakened to the fact that the free camp attracts elements not wanted, and the number of these camps is gradually decreasing. However, the number of private tourist camps operated for profit is rapidly increasing These camps have for rent furnished cottages equipped with modern conveniences In nearly every instance camps of this character are kept in a good sanitary condition, as the owners are desirous of gaining State approval as a means of increasing their patronage.

"Insanitary tourist camps are a health menace of no minor magnitude. New York and a few other States have made additions to their sanitary codes which give their State boards of health effectual

jurisdiction over all tourist camps and swimming pools within their respective States. Such an addition to the Texas sanitary code would be very helpful."

VACCINATION PROTECTS

Although the efficacy of vaccination and revaccination in preventing individuals from contracting smallpox is now accepted by all scientific workers in the field of disease prevention, frequently there occur small outbreaks among family groups or other close contacts which bring out so vividly the protection afforded by this simple prophylactic measure that they are worthy of notice The report printed below, a typical example of many such instances, is taken from the Sanitary Bulletin for September, 1926, published by the Department of Health, of Buffalo, N. Y

The following report by the New York Department of Health is a clean-cut illustration of the value of vaccination On July 30 a young colored man visited the department of health to consult a physician regarding a skin eruption which had broken out on his body Upon examination he gave a history of having been taken ill on July 21 with fever and headache, which persisted until July 24, when the symptoms subsided and a first rash appeared. He returned to work but was referred to the health department for diagnosis. Examination showed a pustular eruption on the face, body, and extremities The history of the sickness before the appearance of the rash and the remission of symptoms, as was also the distribution of the eruption, were typical of smallpox. The patient had never been vaccinated Investigation was then made at his home and a recovered case of smallpox was found in a woman 23 years of age who lived in the same family. This case had never been diagnosed nor reported nor had the patient ever been vaccinated. Further examination disclosed a third man, 23 years of age, who had visited the two cases mentioned, and who had also just recovered from smallpox which had not been diagnosed nor reported to the health department, nor had he been vaccinated He was apparently the cause of the infection in the preceding two cases Interesting facts in connection with these two cases are that at the home of the first cases there were four persons exposed; two of these showed signs of successful vaccination and they escaped the disease; the other two, as stated in the history, had never been vaccinated and contracted the disease. The wife of the third case found upon investigation showed signs of two successful vaccinations, and though in most intimate contact with the patient during the entire period of infection she escaped the disease. Out of five persons exposed, therefore, the only two who contracted the disease were those who had never been vaccinated.

These cases demonstrate the lesson learned in thousands of experiences that successful vaccination and revaccination is the potent and easy method of eradicating smallpox.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Public Health in Persia. Dr. A. R Neligan, British representative on the Persian Sanitary Council. *The Lancet*, No. 5351, March 20, 1926, pp. 635–639, No 5352, March 27, 1926, pp 690–694 (Abstract by I W. Mendelsohn.)

On the basis of information obtained from various reports, the writer discusses public health in Persia for the period 1914–1924 under the following headings: Geography and climate, medical education, central sanitary administration, municipal health services, frontiers, pilgrim traffic, quarantine stations, shrines, public vaccination service, hospitals, nursing, Pasteur Institute, epidemic and endemic diseases, plague in the interior, typhus fever and relapsing fever, influenza, malaria, tuberculosis, venereal disease, smallpox, leprosy, other infectious diseases, epizootic diseases.

Physical conditions of Persia —Difficulties experienced in obtaining accurate sanitary information about Persia result from the following conditions: (1) Of 10,000,000 population, 2,000,000 are nomads; (2) the country is mainly an elevated plateau 2,000 to 5,000 feet above the sea, with the central and eastern portion a vast waterless desert; (3) main roads are few and bad, and journeys are slow even by motor car—there are no railways, (4) telegraphic and postal communications are possible only with the larger towns and along the main routes.

Central sanitary administration —The chief sanitary authority is the Persian Sanitary Council which is composed of 12 Persian doctors, representatives of the Persian ministries, the police and customs departments, and medical representatives of the British, American, French, and German legations. The duties of the council are as follows: (1) To act as advisory body to the Persian Government on all questions of public health and international sanitation, (2) to deal with epidemics in the country; (3) to organize and supervise the sanitary defenses of the frontiers; (4) to receive and collate sanitary reports; (5) to carry on public vaccination; (6) to supervise the importation and distribution of morphine, cocaine, and their derivatives. The funds available are very inadequate Medical education in Persia is of a very low standard.

Water supplies.—Some towns obtain their water supplies from wells. In most places water is derived from distant underground springs and is brought in artificial underground channels which gradually approach the surface near the points where the water is required. Thence the water runs in open courses It is drunk as well as used for irrigation and all domestic purposes, including the special ablutions of Mussulmans. It has been found impossible to check the washing of clothes in the water channels.

Sewage disposal.—A simple pit of greater or less depth is still the sole sanitary contrivance in Persia; the soil is absorbent in the greater part of the country Uncared for, as it frequently is, the pit becomes a nuisance and a danger In towns there is a great scarcity of public latrines, and most waste pieces of ground are used as squatting places

Plague and cholera—Persia's three long land frontiers run with those of countries liable to outbreaks of plague and cholera. Pilgrimages and lack of adequate quarantine facilities increase the danger Plague has occurred in several places in Persia in the period under discussion. Cholera is a much more troublesome problem than plague Several epidemics have occurred in Persia in the period under report

Malaria—The most serious disease in Persia by far is malaria. It causes heavy mortality every year and keeps the inhabitants of whole districts in a low physical condition. Along the Caspian Sea on the north is a belt of rice, cotton, and marsh country, varying from 2 to 40 miles in width, with dense forest. The rainfall is high There are numerous rivers, moderate temperatures, mist, perpetual dampness, and rank vegetation

On the plateau there are heavily infected districts due to water storage and irrigation methods and the nature of the rivers. In towns such as Teheran every house and every garden has at least one tank for irrigation, domestic purposes, and religious ablutions. In addition, many houses have underground cisterns for storing drinking water, which are filled from surface channels. All the tanks and cisterns are breeding places for mosquitoes. The plateau rivers end in swamps

Quinine treatment as given by Persian doctors is inadequate. The writer states that he has proved the efficiency of gold fish as as larvicides in experiments made in the garden of the British Legation in 1906.

From the Old Oaken Bucket to a Modern Safe Water Supply. J. A. Jensen, Supervisor, Water Works, Minneapolis, Minn. *American City*, vol. 35, No 3, September, 1926, pp. 323–325. (Abstract by A. S. Bedell.)

In a brief review of the advance in water-works practice during the last thirty years, the writer indicates clearly the broad and complicated field of endeavor in the water works business, and the need for properly qualified, versatile men capable of keeping step with the advancement and progress of the art.

Typhoid in City and Country. Charles N. Leach and Kenneth F. Maxcy. *Water Works*, vol. 65, No. 6, June 9, 1926, pp. 295–296. (Abstract by E. C. Sullivan.)

A study of typhoid fever was made in Alabama in an attempt to establish its relative incidence in population units of various sizes Knowing the epidemiology of typhoid fever, it would be suspected that the highest incidence would be found in the small town—that unit of population where communal living is most primitive and sanitary safeguards are least in evidence. The results of the analysis of the data, including tabular presentation, are published in this article.

From inspection of the tables it is found that the highest incidence of typhoid fever in Alabama, as gauged by both morbidity and mortality, is found in the small unincorporated towns having a population of 500 to 1,000 With the towns of successively larger population, the rates become progressively smaller, reaching a minimum figure in the three largest cities of the State In direct contrast to the high rate of the small towns is the low rate in the country districts and the small unincorporated communities The rate of this last group is as low as that in the large cities.

The most fruitful field for typhoid reduction is the small incorporated town. In Alabama, although contributing only 7 per cent of the total population of the State, these communities furnish annually 28 per cent of the typhoid fever cases. . The population living in the unincorporated towns and country districts, having comparative protection by virtue of their very lack of contact with their fellowmen and constituting 71 per cent of the total population of the State, contribute only 41 per cent of the annual typhoid fever toll. The risk of typhoid fever in this part of the population would appear to be no greater than that of persons living in the large and relatively large cities.

Less Typhoid Fever During 1925. Anon , *Health News*, New-York State Health Department, vol. 3, No 22, May 31, 1926, p. 85. (Abstract by Isador W Mendelsohn.)

In 1925, seven typhoid fever outbreaks in New York State were due to infected milk and two to polluted water. Thirty typhoid carriers were discovered, to which 122 primary and 7 secondary cases of the disease were attributed There were 1,483 up-State cases against 1,602 in 1924, giving a case rate of 28 per 100,000 population.

Studies of the Epidemiology of Malaria in the Coastal Lowlands of Brazil, Made Before and After the Execution of Control Measures. Mark F. Boyd. Reprinted from the *American Journal of Hygiene*, Monographic Series, No 5, May, 1926. (Abstract by K. F. Maxcy.)

The object of this study was "to ascertain a simple, economical, and effective method of malaria control adapted to a tropical area, which will offer prospects of permanent relief with a minimum of maintenance." The report contains an outline of the data collected during three years of investigation.

Four towns in the lowlands adjacent to Guanabara Bay in the State of Rio de Janeiro were selected. Topographical, climatic, demographic, sociologic, and economic factors are discussed in their relationship to the local malaria problem.

Anophelines of the coastal zone of Brazil are reviewed. On the basis of relative numbers, seasonal prevalence, association with human habitations, blood meal preference, and dissections, it is concluded that *A argyritarsis* is the principal propagator of malaria and that *A tarsimaculatus* plays a secondary rôle Eight other species of *Anopheles* are found in the area, but are unimportant as vectors.

The prophylactic work was based on the belief that the soundest method for the solution of a malaria problem is an attack on the larval stages of the transmitting species of anophelines (species control), within a 1-kilometer zone about the population center to be protected. In addition to the antilarval work, a considerable amount of quinine was distributed, free of charge, in three of the four areas

The costs of various enterprises in ditching, filling, stream cleaning, etc , and the maintenance required, are given The drainage executed was exclusively by means of open ditches at a cost of from $88 to $107 per kilometer (current rate of exchange).

Next to drainage, top minnows, *Poecilia vivipara*, were probably the most important factor in degree of "spontaneous" larval control secured. The use of oil was most widespread, though paris green was found valuable in certain areas The author emphasizes the necessity of using an unadulterated paris green.

Splenic and parasitic indices were made at approximately six-month intervals. The first three were taken before the initiation of control measures, the fourth and fifth were taken during the progress and at the close of the first year (1924) of control work; the last during the height of the malaria season in the spring of 1925.

In Magé, population 2,255, an area of light endemicity, the spleen rate at successive surveys was 6, 12, 5, 2, 3. The cost of the work during the first year was about $1 60 per capita, and of maintenance, second year, about $0.70. It is concluded that, owing to the work done and to favorable natural conditions, a very decided reduction in malaria transmission was effected which was well worth the money and effort expended.

In Itamby, population 450, an area of moderately high endemicity, the spleen rates at successive surveys were 73, 77, 75, 77, 73, 43; the per capita costs were, first year, $5.50; second year, $2 The results are regarded by the author as highly satisfactory.

In Porto das Caixas, population 457, about the same sort of area, the spleen rates were 78, 86, 85, 72, 67, 75; the per capita costs, first year, $6; second year, $3. The degree of malaria control achieved was not in proportion to the effort.

In Sant' Anna, population 198, considered to have the most intense degree of endemicity, the successive spleen indices were 76, 85, 72, 66, 75, and 74. Only one year of control work was attempted and this cost about $3 per capita The results were considered unsatisfactory.

(Abstractor's Note: In general, so far as the coastal region of tropical Brazil is concerned, one gathers from this elaborate report that the question propounded in the beginning is answered in the negative. In a town where the disease is lightly endemic and little transmission taking place, the disease may be virtually eradicated at a reasonable cost by antilarval measures and the liberal distribution of quinine In areas of moderate or high endemicity, some degree of reduction in malaria may be effected, but the eradication of the disease is not economically possible with present knowledge and the low per capita wealth)

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for August, 1926

The accompanying table is taken from the Statistical Bulletin for September, 1926, published by the Metropolitan Life Insurance Co , and presents the mortality experience of the industrial insurance department of the company for August, 1926, as compared with July, 1926, and with August and year, 1925. The rates are based on a strength of approximately 17,000,000 insured persons in the industrial populations of the United States and Canada. The annual death rates for all causes in this group are lower than those for the general population. For the years 1920–1924 they were from 71 to 75 per cent of the rates for the Registration Area.

The Bulletin states:

The death rate in the industrial populations of the United States and Canada, in August, declined slightly as compared with the preceding month This reflects the usual seasonal improvement that is observed at this time of the year. Compared with August, 1925, there was an increase from a rate of 7 6 per 1,000 to 7.9.

The table shows higher rates in August than prevailed a year ago for every cause of major numerical importance, although in no case is there a marked rise in the mortality. For August and each of the two months immediately preceding, the tuberculosis death rate increased over last year, and the cumulative rate for tuberculous disease is now substantially the same as at this time last year. It is now possible that 1926 will break the long sequence of years which have shown year-to-year drops in the tuberculosis death rate. * * * The reduction in the tuberculosis rate has been marked during several decades, and the time was bound to come when either a decided retardation in the velocity of the decline would be experienced, or a new low point established which could not be bettered for some years to come. In so far as can be judged by an analysis of data available at this time, the failure to improve over last year's tuberculosis

death rate is due, entirely, to an increase among the colored policyholders Up to the end of June, there was a drop of 2 8 per cent from the corresponding figure of 1925 among the white industrial population of the United States and Canada.

It is predicted that a considerable reduction will be shown in 1926 in the death rate for diarrheal diseases, as in each of the three months in which these conditions are most prevalent—June, July, and August—the rate declined markedly from the figure recorded last year.

A decline is also shown in the death rate for puerperal conditions.

Automobile fatalities in this group were fewer in August and July than during the corresponding months of 1925; and up to the week ended September 18 the cumulative death rate for automobile accidents was slightly lower than that for the corresponding period of last year. The improvement, however, in July and August is to be credited for this showing, since the first six months of this year recorded the usual increase in this cause of death.

Death rates (annual basis) for principal causes per 100,000 lives exposed, July and August, 1926, and August and year, 1925

[Industrial department, Metropolitan Life Insurance Co]

[1] Annual rate per 1,000 population
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 63 cities
[4] Deaths for week ended Friday, Oct 15, 1926
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population Atlanta 31, Baltimore, 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Kansas City, Kans, 14, Louisville 17, Memphis 38, Nashville 30, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D. C, 25

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended October 23, 1926

ALABAMA

	Cases
Cerebrospinal meningitis	1
Chicken pox	1
Dengue	1
Diphtheria	101
Influenza	86
Malaria	147
Measles	6
Mumps	2
Pellagra	5
Pneumonia	20
Poliomyelitis	1
Scarlet fever	35
Smallpox	3
Tetanus	2
Tuberculosis	37
Typhoid fever	41
Typhus fever	3
Whooping cough	16

ARIZONA

Chicken pox	1
Measles	10
Tuberculosis	15

ARKANSAS

Chicken pox	3
Diphtheria	12
Influenza	22
Malaria	101
Measles	4
Paratyphoid fever	1
Pellagra	5
Poliomyelitis	2
Scarlet fever	5
Smallpox	1
Tuberculosis	3
Typhoid fever	31
Whooping cough	15

CALIFORNIA

	Cases
Cerebrospinal meningitis	
Fresno County	1
Oakland	1
Chicken pox	148
Diphtheria	117
Influenza	10
Jaundice	2
Leprosy—San Bernardino County	1
Lethargic encephalitis—Glendale	1
Measles	507
Poliomyelitis	
Humboldt County	1
Los Angeles County	2
San Bernardino County	1
San Diego	1
Ventura County	1
Scarlet fever	192
Smallpox	7
Tuberculosis	191
Typhoid fever	13
Whooping cough	58

COLORADO

Chicken pox	15
Diphtheria	20
Malaria	1
Measles	1
Pneumonia	2
Scarlet fever	47
Tuberculosis	42
Typhoid fever	5
Vincent's angina	2
Whooping cough	4

CONNECTICUT

Chicken pox	49
Diphtheria	26
German measles	2
Lethargic encephalitis	1

CONNECTICUT—continued

	Cases
Measles	20
Mumps	1
Paratyphoid fever	1
Pneumonia (broncho)	13
Pneumonia (lobar)	14
Poliomyelitis	1
Scarlet fever	31
Septic sore throat	2
Tuberculosis (pulmonary)	27
Typhoid fever	4
Whooping cough	29

DELAWARE

Chicken pox	3
Diphtheria	2
Malaria	1
Ophthalmia neonatorum	1
Pneumonia	1
Scarlet fever	14
Tuberculosis	2
Typhoid fever	4
Whooping cough	1

FLORIDA

Dengue	1
Diphtheria	52
Influenza	1
Malaria	16
Measles	3
Mumps	1
Paratyphoid fever	3
Pneumonia	2
Scarlet fever	5
Smallpox	2
Tetanus	1
Trachoma	1
Tuberculosis	26
Typhoid fever	24
Typhus fever	2
Whooping cough	3

GEORGIA

Cerebrospinal meningitis	1
Chicken pox	12
Dengue	1
Diphtheria	99
Dysentery	6
Hookworm disease	1
Influenza	40
Malaria	135
Measles	3
Mumps	2
Pellagra	2
Pneumonia	20
Scarlet fever	21
Septic sore throat	16
Smallpox	12
Tuberculosis	13
Typhoid fever	55
Typhus fever	1
Whooping cough	9

IDAHO

Cerebrospinal meningitis—Weiser	1
Chicken pox	19
Diphtheria	3
Measles	11
Scarlet fever	28
Typhoid fever	1
Whooping cough	1

ILLINOIS

	Cases
Cerebrospinal meningitis	
Madison County	1
Winnebago County	1
Chicken pox	157
Diphtheria	123
Influenza	11
Lethargic encephalitis	
Brown County	1
Cook County	2
Effingham County	1
Kankakee County	1
Measles	178
Mumps	27
Pneumonia	150
Poliomyelitis	
Cook County	2
Henry County	1
Macon County	1
McHenry County	1
Scarlet fever	199
Tuberculosis	429
Typhoid fever	87
Whooping cough	196

INDIANA

Chicken pox	80
Diphtheria	117
Influenza	13
Measles	17
Pneumonia	6
Poliomyelitis	2
Scarlet fever	131
Smallpox	26
Tuberculosis	34
Typhoid fever	43
Whooping cough	44

IOWA

Chicken pox	33
Diphtheria	34
German measles	1
Impetigo contagiosa	1
Measles	15
Mumps	4
Scarlet fever	36
Smallpox	3
Tuberculosis	22
Typhoid fever	12
Vincent's angina	1
Whooping cough	7

KANSAS

Cerebrospinal meningitis	
Hope	1
Hutchinson	1
Mulvane	1
Chicken pox	32
Diphtheria	44
Influenza	1
Malaria	1
Measles	52
Mumps	15
Pneumonia	11
Scarlet fever	62
Smallpox	4
Tuberculosis	40
Typhoid fever	20
Whooping cough	24

LOUISIANA

	Cases
Cerebrospinal meningitis	1
Diphtheria	36
Influenza	12
Malaria	32
Pneumonia	24
Scarlet fever	15
Tuberculosis	38
Typhoid fever	23
Whooping cough	4

MAINE

	Cases
Chicken pox	29
Diphtheria	6
Impetigo contagiosa	14
Influenza	8
Measles	40
Mumps	13
Pneumonia	13
Poliomyelitis	1
Scarlet fever	29
Tuberculosis	6
Typhoid fever	10
Whooping cough	51

MARYLAND[1]

	Cases
Cerebrospinal meningitis	1
Chicken pox	42
Diphtheria	47
Dysentery	6
German measles	6
Influenza	7
Malaria	1
Measles	7
Mumps	7
Paratyphoid fever	1
Pneumonia (broncho)	15
Pneumonia (lobar)	13
Poliomyelitis	2
Scarlet fever	37
Septic sore throat	1
Tuberculosis	22
Typhoid fever	47
Typhus fever	1
Whooping cough	43

MASSACHUSETTS

	Cases
Chicken pox	84
Conjunctivitis (suppurative)	1
Diphtheria	69
Dysentery	1
German measles	6
Influenza	4
Lethargic encephalitis	3
Malaria	1
Measles	39
Mumps	62
Ophthalmia neonatorum	34
Pneumonia (lobar)	44
Poliomyelitis	9
Scarlet fever	170
Septic sore throat	2
Trachoma	1
Tuberculosis (pulmonary)	90
Tuberculosis (other forms)	27
Typhoid fever	16
Whooping cough	70
Diphtheria	191

[1] Week ended Friday.

MICHIGAN

	Cases
Measles	30
Pneumonia	58
Scarlet fever	140
Smallpox	8
Tuberculosis	134
Typhoid fever	22
Whooping cough	107

MINNESOTA

	Cases
Chicken pox	81
Diphtheria	81
Influenza	2
Lethargic encephalitis	1
Measles	63
Pneumonia	3
Scarlet fever	20
Smallpox	7
Tuberculosis	40
Typhoid fever	5
Whooping cough	15

MISSISSIPPI

	Cases
Cerebrospinal meningitis	1
Diphtheria	29
Poliomyelitis	2
Scarlet fever	11
Smallpox	14
Typhoid fever	23

MISSOURI

	Cases
Cerebrospinal meningitis	2
Chicken pox	8
Diphtheria	77
Influenza	11
Malaria	5
Measles	16
Mumps	2
Pneumonia	1
Poliomyelitis	1
Scarlet fever	55
Smallpox	4
Trachoma	1
Typhoid fever	27
Whooping cough	12

NEBRASKA

	Cases
Cerebrospinal meningitis	1
Chicken pox	4
Diphtheria	6
Measles	4
Mumps	3
Scarlet fever	25
Smallpox	54
Typhoid fever	1
Whooping cough	8

NEW JERSEY

	Cases
Cerebrospinal meningitis	2
Chicken pox	98
Diphtheria	118
Influenza	[illegible]
Malaria	1
Measles	15
Pneumonia	51
Poliomyelitis	3
Scarlet fever	73
Typhoid fever	33
Whooping cough	96

NEW MEXICO

	Cases
Chicken pox	2
Conjunctivitis	2
Diphtheria	3
Measles	2
Mumps	1
Pneumonia	6
Rabies (in animals)	1
Scarlet fever	13
Smallpox	1
Tuberculosis	24
Typhoid fever	6
Whooping cough	1

NEW YORK

(Exclusive of New York City)

	Cases
Cerebrospinal meningitis	4
Chicken pox	170
Diphtheria	80
Dysentery	4
German measles	35
Influenza	1
Lethargic encephalitis	1
Malaria	3
Measles	236
Mumps	79
Ophthalmia neonatorum	1
Pneumonia	118
Poliomyelitis	23
Scarlet fever	57
Smallpox	5
Tetanus	8
Typhoid fever	53
Vincent's angina	8
Whooping cough	150

NORTH CAROLINA

	Cases
Chicken pox	21
Diphtheria	158
German measles	4
Malaria	4
Measles	5
Poliomyelitis	2
Scarlet fever	73
Septic sore throat	4
Smallpox	7
Typhoid fever	11
Whooping cough	141

OKLAHOMA

(Exclusive of Oklahoma City and Tulsa)

	Cases
Diphtheria	55
Influenza	76
Malaria	84
Pneumonia	13
Poliomyelitis—Tulsa County	1
Scarlet fever	30
Smallpox	3
Typhoid fever	92
Whooping cough	16

OREGON

	Cases
Chicken pox	13
Diphtheria	20
Influenza	12
Measles	[illegible]
Mumps	3
Pneumonia	[2] 6
Poliomyelitis	1
Scarlet fever	45
Septic sore throat	2
Smallpox	13
Tuberculosis	[2] 1
Typhoid fever	11
Whooping cough	6

[2] Deaths.

PENNSYLVANIA

	Cases
Chicken pox	173
Diphtheria	146
German measles	4
Impetigo contagiosa	49
Lethargic encephalitis—Philadelphia	1
Malaria	1
Measles	262
Mumps	30
Ophthalmia neonatorum—Philadelphia	2
Pellagra—Pittsburgh	1
Pneumonia	35
Poliomyelitis	
Bradford	1
Clintonville	2
Scattering	6
Scabies	5
Scarlet fever	186

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended October 9, 1926, 35 States reported 1,602 cases of diphtheria For the week ended October 10, 1925, the same States reported 1,720 cases of this disease. Ninety-seven cities, situated in all parts of the country and having an aggregate population of more than 30,150,000, reported 921 cases of diphtheria for the week ended October 9, 1926. Last year for the corresponding week they reported 763 cases. The estimated expectancy for these cities was 1,017 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics

Measles—Thirty-two States reported 1,020 cases of measles for the week ended October 9, 1926, and 539 cases of this disease for the week ended October 10, 1925 Ninety-seven cities reported 180 cases of measles for the week this year, and 304 cases last year.

Poliomyelitis—The health officers of 35 States reported 88 cases of poliomyelitis for the week ended October 9, 1926. The same States reported 217 cases for the week ended October 10, 1925.

Scarlet fever—Scarlet fever was reported for the week as follows: Thirty-five States—this year, 1,773 cases; last year, 1,269 cases, 97 cities—this year, 646 cases; last year, 526 cases; estimated expectancy, 564 cases.

Smallpox.—For the week ended October 9, 1926, 35 States reported 123 cases of smallpox. Last year for the corresponding week they reported 97 cases. Ninety-seven cities reported smallpox for the week as follows: 1926, 15 cases; 1925, 30 cases; estimated expectancy, 29 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—One thousand and forty-eight cases of typhoid fever were reported for the week ended October 9, 1926, by 34 States. For the corresponding week of 1925, the same States reported 1,021 cases of this disease Ninety-seven cities reported 192 cases of typhoid fever for the week this year and 205 cases for the corresponding week last year. The estimated expectancy for these cities was 197 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 92 cities, with a population of more than 29,530,000, as follows; 1926, 382 deaths; 1925, 364 deaths.

City reports for week ended October 9, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria: Cases, estimated expectancy	Diphtheria: Cases reported	Influenza: Cases reported	Influenza: Deaths reported	Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended October 9, 1926, compared with those for a like period ended October 10, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than

29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, September 5 to October 9, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Aden, Jeddah.
Iraq.—Basra.
Persia.—Mohammerah, Bender Abbas, Bushire.
British India.—Chittagong, Cochin, Vizagapatam, Tuticorin.
Federated Malay States.—Port Swettenham.
Straits Settlements.—Singapore, Penang.
Dutch East Indies.—Batavia, Surabaya, Samarang, Belawan Deli, Palembang, Sabang, Makassar, Banjermasin, Tarakan, Padang Balik-Papan, Samarinda, Pontianak, Menado.
Sarawak.—Kuching.
British North Borneo.—Sandakan, Jasselton, Kudat, Tawao.
Portuguese Timor.—Dilly.
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.
French Indo-China.—Saigon and Cholon, Turane, Haiphong.
China.—Hong-Kong.
Formosa.—Keelung.
Japan.—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki.
Korea.—Chemulpo, Fusan.
Manchuria.—Mukden, Changchun, Harbin.
Kwantung.—Port Arthur, Dairen.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Garnarvon, Thursday Island.
New Guinea.—Port Moresby.
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea.
Fiji.—Suva.
Hawaii.—Honolulu.
Society Islands.—Papeete.

AFRICA

Egypt.—Port Said, Suez.
Anglo-Egyptian Sudan.—Port Sudan, Suakin.
Eritrea.—Massaua.
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Mogadiscio.
Kenya.—Mombasa.
Tanganyika.—Dar-es-Salaam.
Seychelles.—Victoria.
Mauritius.—Port Louis.
Portuguese East Africa.—Mozambique, Beira, Lorenço-Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Calcutta.
Madagascar.—Tamatave, Majunga.

ALGERIA

Plague.—Oran—Information dated October 1, 1926, shows the occurrence of five cases of plague with one death at Oran, Algeria.

BOLIVIA

Communicable diseases—La Paz—*August, 1926*.—During the month of August, 1926, communicable diseases were reported at La Paz, Bolivia, as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Cerebrospinal meningitis		1	Scarlet fever		7
Diphtheria	8	6	Smallpox	14	4
Dysentery	34	6	Tuberculosis	18	9
Influenza	38	12	Typhoid fever	15	3
Measles	12	2	Typhus fever	9	1
Pneumonia	20	8	Whooping cough	16	4
Poliomyelitis	5	1			

Population, estimated, 100,000.

CANADA

Communicable diseases—Weeks ended October 2, and 9, 1926—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the weeks ended October 2, and 9, 1926, as follows:

WEEK ENDED OCTOBER 2

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal meningitis				1				1
Influenza	7							7
Lethargic encephalitis				2				2
Poliomyelitis				5				5
Smallpox				2		1	15	18
Typhoid fever	3	5	57	23	5		1	94

WEEK ENDED OCTOBER 9

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total

Typhoid fever	3	9	10	19	3	6	2	52

Chosen

Cholera—Shingishu and vicinity—Precautions against spread of infection.—Cholera has been reported present in Shingishu and vicinity, Chosen, the first case having been notified September 9, 1926. Under date of September 13, it was stated that a Government order had been issued declaring a definite area along the Yalu River between Shingishu and Antung to be cholera infected and requiring strict enforcement of quarantine within that area. It was stated that preventive measures were being observed at open ports and that foot and railway travel from Antung had been made subject to medical inspection for all persons suspected of cholera infection.

CZECHOSLOVAKIA

Communicable diseases—August, 1926.—During the month of August, 1926, communicable diseases were reported in the Republic of Czechoslovakia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	4		Puerperal fever	34	15
Cerebrospinal meningitis	14	5	Rabies	2	2
Diphtheria	267	28	Scarlet fever	706	13
Dysentery	206	7	Trachoma	142	
Malaria	66		Typhoid fever	844	46

ECUADOR

Plague—Guayaquil—September 1-30, 1926.—During the month of September, 1926, four cases of plague were reported at Guayaquil, Ecuador

Plague-infected rats.—During the same period, of 21,223 rats taken at Guayaquil, 30 rats were found plague infected.

ESTHONIA

Communicable diseases—August, 1926.—During the month of August, 1926, communicable diseases were reported in the Republic of Esthonia as follows:

Disease	Cases	Disease	Cases
Diphtheria	19	Scarlet fever	110
Leprosy	2	Tuberculosis	157
Measles	73	Typhoid fever	38
Paratyphoid fever	16		

Population, census of 1922, 1,107,059

GERMANY

Typhoid fever epidemic—Hanover—September, 1926.—Information dated September 18, 1926, received from Bremen, Germany, shows epidemic typhoid fever prevalence in the city of Hanover, Germany, in September, 1926, with 10 cases reported September 8, 60 cases September 9, and on September 10, 150 cases received at the city hospital. The number of cases was then stated to be increasing at a rate of about 150 per day, with a total of 1,504 cases under treatment and 42 fatalities to September 17.

The cause of the outbreak had not been determined. Free inoculation stations were established, and about 10,000 voluntary inoculations were reported.

SIAM

Quarantine against ports in Indo-China suspended.—Quarantine measures against arrivals from Saigon and Cholon, Indo-China, at ports in Siam, were removed by quarantine circular dated August 23, 1926.

SYRIA

Plague—Beirut—October 15, 1926.—Plague was reported present at Beirut, Syria, October 15, 1926.

VIRGIN ISLANDS

Communicable diseases—September, 1926—During the month of September, 1926, communicable diseases were reported in the Virgin Islands of the United States as follows:

Island and disease	Cases	Remarks
St Thomas and St John		
Chancroid	5	Imported, 1
Fish poisoning	3	
Gonorrhea	12	Imported, 1

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of diesase (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM
THE SUPERINTENDENT OF DOCUMENTS

PUBLIC HEALTH REPORTS

VOL. 41 NOVEMBER 5, 1926 NO. 45

A CASE OF TYPHUS-LIKE FEVER FOLLOWING TICK BITE

By R R Spencer, Surgeon, United States Public Health Service

Following is the report of a case of typhus-like fever following a tick bite, investigated by the writer, who was detailed for the purpose by the United States Public Health Service on August 16, 1926:

S P, age 35, wife of a butcher in Norfolk, Va, was bitten on the inner left thigh, the left buttock, and the lower right abdomen by a tick which came from a calf hide shipped from North Carolina or Virginia

At each point of the tick bite, swelling, redness, and a small ulcer developed The tick was destroyed Similar ticks had often been noticed by the butcher and his family; and occasionally a tick had bitten one of them, but never before had any illness followed

On July 15, 10 days after the tick bite, the patient had a chill, fever, severe headache, and muscular and joint pains all over the body. Two days later, fever and prostration being marked, she called her physician, and on the 20th was removed to a hospital On the same day, the attending physician noted a faint, pinkish rash over the chest and abdomen The rash faded and reappeared on Sunday, July 25, becoming more definite and purplish and at that time covering all parts of the body except the face. Upon admission the patient showed extreme prostration and registered a temperature of 105° F.

Physical examination.—(July 28) the patient was a stout woman. The face was flushed, the conjunctivae were congested and watery, the expression was anxious, and the mental condition dull. Questions were answered slowly; mental concentration was obviously difficult The tongue was very dry and coated. There were no nits or evidence of lice in the head or clothing Lice had been carefully looked for upon admission

Over the chest, back, and extremities, including palms and soles, there was a fine petechial rash appearing in discrete, irregular macules, some of which would disappear upon pressure The majority were distinctly hemorrhagic in type and did not disappear upon pressure.

The heart and lungs were apparently normal

The abdomen was large and flabby and a distinct movable mass could be felt in the lower right quadrant There was no indication that this mass was in any way connected with the present illness.

The spleen was not readily palpable because of the excessive abdominal fat.

The inguinal glands on both sides were palpable and slightly tender Small healing ulcers were still present on the lower right abdomen, left inner thigh, and left buttock, at the points of the tick bite

Laboratory findings—Urine examinations of catherized specimens, made on July 21, 24, and 26, showed some albumin, fine granular casts, and a few pus cells.

The blood picture on July 20 showed white blood cells 5,600; a normal differential count, and smears were negative for blood parasites

On July 21, the Widal was negative and a blood culture was negative

On July 22, stool was negative for parasites

On July 24, white blood cells, 8,800; small mononuclears 10 per cent; large mononuclears 10 per cent, polymorphonuclears 89 per cent Blood serum taken from the patient on July 25 and 28 and August 6 did not agglutinate *B. proteus* X_{19} or *B. tularense* The sample taken on July 28 also gave negative agglutination for *B. eberthi* and *B. abortus*

On July 28, the 13th day of fever, six guinea pigs were injected intraperitoneally with whole citrated blood of the patient, each animal receiving 2 c. c. Only one of these guinea pigs developed fever, which began on the 13th day after injection. Transfer of blood from this pig to other guinea pigs and to a monkey were made with entirely negative results.

The patient's fever continued for three weeks There was no definite crisis; convalescence was slow and there were no sequelae.

Discussion—The clinical aspects of this case, in nearly every detail, suggested typhus fever, although it was not supported by the laboratory findings. Failure of the serum to agglutinate *B. proteus* X_{19} and the negative results of animal inoculation do not, however, exclude typhus fever.

Rocky Mountain spotted fever was considered, but the negative animal inoculations and the locality make such a diagnosis very doubtful.

Other ticks similar to the one that had bitten the patient were secured and proved to be *Amblyomma americanum*. This tick is an occasional parasite of man, but has never been implicated in the transmission of disease. The tick bites may have been coincidental; but because the bites caused local sores and glandular enlargement preceding the onset of fever, one can not ignore their possible significance.

The case is reported because of the association of the illness with tick bites, the consistently negative agglutination of *B proteus* X_{19}, and the failure to reproduce the disease in laboratory animals.

SYMPOSIUM ON THE PREVENTION AND CURE OF CANCER

A symposium on cancer control was held at Lake Mohonk, N Y., September 20–24, 1926, under the auspices of the American Society for the Control of Cancer The purpose of the meeting was to consider the prevention and cure of cancer from a practical standpoint, to crystalize existing knowledge, and to express in concise language the fundamental ground-work in fact and opinion upon which the collective effort now being made in the United States and other countries for the control of cancer should be continued and extended

The symposium was attended by distinguished workers in the field of cancer control from both this country and Europe, and a fund of information and opinion was presented upon which the society will base its plans for the conduct of its work for many years to come

Two resolutions were passed by the delegates The first resolution pertained to the development of measures for continuation of the international effort to unify and disseminate knowledge regarding the control of cancer. The second was the adoption of statements of facts and opinions which should form the basis for campaigns against the disease The text of this statement given below is taken from the Health News for October 18, 1926, published by the New York State Department of Health

Although the present state of knowledge of cancer is not sufficient to permit of the formulation of such procedures for the suppression of this malady as have been successfully employed for the control of infectious diseases, there is enough well-established fact and sound working opinion concerning the prevention, diagnosis, and treatment of cancer to save many lives, if this information is carried properly into effect

1 The causation of cancer is not completely understood, but it may be accepted that, for all practical purposes, cancer is not to be looked upon as contagious or infectious.

2. Cancer itself is not hereditary, although a certain predisposition or susceptibility to cancer is apparently transmissible through inheritance This does not signify that, because one's parent or parents or other members of the family have suffered from cancer, cancer will necessarily appear in other persons of the same or succeeding generation

3 The control of cancer, so far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which depends upon the intelligent cooperation of the patient and physician.

4. Persons who have cancer must apply to competent physicians at a sufficiently early stage in the disease, in order to have a fair chance of cure This applies to all forms of cancer. In some forms early treatment affords the only possibility of cure.

5. Cancer in some parts of the body can be discovered in a very early stage, and if these cases are treated properly the prospect for a permanent cure is good.

6 The cure of cancer depends upon discovering the growth before it has done irreparable injury to a vital part of the body and before it has spread to other parts. Therefore, efforts should be made to improve the methods of diagnosis in these various locations and the treatment of the cancers so discovered.

7 The public must be taught the earliest danger signals of cancer which can be recognized by persons without a special knowledge of the subject, and induced to seek competent medical attention when any of these indications are believed to be present.

8. Practitioners of medicine must keep abreast of the latest advances in the knowledge of cancer in order to diagnose as many as possible of the cases of cancer which come to them

9 Surgeons and radiologists must make constant progress in the refined methods of technic which are necessary for the diagnosis and proper treatment not only of ordinary cases but of the more obscure and difficult ones.

10 There is much that medical men can do in the prevention of cancer, in the detection of early cases, in the referring of patients to institutions and physicians who can make the proper diagnosis and apply proper treatment, when the physicians themselves are unable to accomplish these results. The more efficient the family doctor is, the more ready he is to share responsibility with a specialist

11. Dentists can help in the control of cancer by informing themselves about the advances in the knowledge of the causes of cancer, especially with relation to the irritations produced by imperfect teeth and improperly fitting dental plates. They can also help by referring cases of cancer which they discover to physicians skilled in the treatment of cancer in this location. It may be doubted whether all dentists fully realize the help which can be obtained from X-ray photographs in revealing not only the state of the teeth but the condition of the bone surrounding them.

12 Medical students should be instructed in cancer by the aid of actual demonstrations of cancer patients, and this to a sufficient extent to give them a good working knowledge of the subject.

13 The most reliable forms of treatment, and, in fact, the only ones thus far justified by experience and observation, depend upon surgery, radium, and X rays.

14. Emphasis should be placed upon the value of the dissemination of the definite, useful, and practical knowledge about cancer, and this knowledge should not be confused nor hidden by what is merely theoretical and experimental.

15 Efforts toward the control of cancer should be made in two principal directions: (1) The promotion of research in order to increase the existing knowledge of the subject, and (2) the practical employment of the information which is at hand Even with our present knowledge many lives could be saved which are sacrificed by unnecessary delay.

At a dinner to the foreign guests held in New York City at the end of the symposium, Dr. William H. Welch, director of the Institute of Hygiene and Public Health, Johns Hopkins University, said:

"The great note struck at the Mohonk symposium was the tremendous importance of the cancer question and the appalling problems which it presents. There was never a time when tuberculosis

presented problems of such magnitude * * * There is no disease to which larger additions to our knowledge have been made than cancer, but because this knowledge does not reach the public which we are most anxious to reach, this seems trivial "

In a recent issue of Campaign Notes of the American Society for the Control of Cancer, the following statements appeared:

Few people realize the seriousness of the cancer problem According to recent statistics issued by the United States Census Bureau, 1 in every 10 adults now living in the United States is destined to die of cancer. Between the ages of 45 and 65 one in every five deaths among women is due to this disease Cancer is now a greater menace to adult life than tuberculosis, and its death rate is rapidly increasing.

Cancer is in many respects a unique disease Against it no sanitary or public health measures have any effect It is not affected by preventive measures such as are employed against infectious diseases. The upbuilding of the general bodily health and economic conditions are incapable of reducing its prevalence.

The only effective measures which now offer any promise are personal ones. People must learn the symptoms and apply to a competent physician upon the first suspicion of the presence of cancer. On their part physicians must give prompt and skillful attention to the patients who come to them There must be a widespread campaign to teach the public what everyone should know about cancer, and a dissemination among medical practitioners of information that will help them in diagnosing and treating their cases

Nothing less than the utmost authority and the most reliable opinion will suffice to meet the pessimistic attitude of many people who think that cancer is incurable, hereditary, and infectious. The strongest argument possible must be presented to convince the man in the street who is inclined to listen to the claims of quacks who hold out a prospect of cure, until the disease is too far advanced to make skillful help of any use

MALARIA IN THE PRAIRIE RICE REGIONS OF LOUISIANA AND ARKANSAS

By M. A Barber, Special Expert, W H W Komp, Associate Sanitary Engineer, and T B Hayne, Technical Assistant, United States Public Health Service

EXTENT AND METHOD OF CULTIVATION OF PRAIRIE RICE

The largest area devoted to the cultivation of prairie rice in the United States is found on that portion of the coastal plain extending approximately from Rayne, La., to Crosby, Tex This area, a large part of which was originally prairie, offers the climate, level ground, relatively impermeable subsoil, and the supply of irrigation water necessary for rice growing. A similar area is found in eastern Arkansas. Of the 904,000 acres of rice grown in the United States in 1925, 450,000 were found in Louisiana and 174,000 in Arkansas.

The cultivation of prairie rice is a comparatively new industry in the United States. Louisiana had about 42,000 acres under cultiva-

tion in 1879, but the greater part of the development in rice culture has occurred since 1889. In Texas practically all of the industry has developed since 1889, and in Arkansas since 1905 With the growth of rice culture, much land formerly considered of little value except for grazing has been brought under cultivation; and this industry has greatly increased the population and wealth of certain parts of the prairie country of the southern United States.

Irrigation is almost universally employed in the cultivation of prairie rice. Water for irrigation is pumped from streams or from deep wells In the Louisiana-Texas area nearly four-fifths of the irrigation water is taken from streams, while in Arkansas practically all of it comes from wells.

During a large part of the growing season the plants stand in shallow water Levees prevent the water from running off and the impermeable subsoil keeps it from seeping away The seed is sown in early May, and the water is usually turned into the fields during that month Drainage for harvest is commonly done in September The majority of the fields are thus kept under water during a period of three or four months in the year Only one crop a year is harvested As a rule the land is used for rice one year and lies fallow or is devoted to other crops during the following year.

The method of cultivation of prairie rice in Arkansas and Louisiana is, then, such as to greatly favor the production of *Anopheles* Large areas are converted into shallow ponds and remain under water during the greater part of the warmer season of the year The water is, for the most part, bright and clear, and is replenished continually with fresh supplies, so that there is no accumulation of products of decay which might pollute the water and render it unfit for anopheline larvæ The fields are exposed to the sun except where the growing rice affords a partial shade, and algæ grow in abundance all over the fields Food and aeration are thus abundantly provided. Grassi has well called rice fields the "Paradise of *Anopheles*." [1]

INCIDENCE OF ANOPHELES IN THE PRAIRIE RICE DISTRICT

The number of larvæ per dip taken up by a dipping pan of standard size gives a rough but useful approximation of the incidence of anopheline larvæ in a breeding place. Two thousand seven hundred and eighty-five dips made by us in the rice fields during the years 1923, 1924, and 1925 gave a total of 2,985 anopheline larvæ, an average of 1.1 per dip. The dips were made with a pan measuring 5 by 9 inches at the top and 3¾ inches in depth We estimated that each dip swept larvæ from an area averaging approximately 50

[1] For many of the statistical facts in relation to rice growing we are indebted to Mr Charles E Chambliss, Associate Agronomist in Charge, Rice Investigations, U S. Department of Agriculture See Farmers' Bulletins No. 1092, February 1920, and No 1356, October, 1925, U S. Department of Agriculture.

square inches Many of the dips were made in more or less selected places, and the average incidence of larvæ was less than 1 1 per 50 square inch; our figures, however, indicate a large production since the breeding area is very great

Larvæ are abundant in the midst of the fields as well as in the ditches inside and outside the dikes More were found in partially open places than where the rice was thick and high They appear early in the season, large collections were made in May. Sometimes good breeding was found in grassy, fallow fields partially flooded through some defect in the dikes

Very large numbers of adult *Anopheles* are found in various resting places throughout the rice district Stables, outhouses, schoolhouses, unscreened dwellings, hollow trees, and similar shelters often swarm with them A single building may contain thousands of them, and surfaces are sometimes blackened by the large numbers of *Anopheles* roosting on them We counted 304 *A quadrimaculatus* resting on a board 12 by 13 inches Le Prince (1) counted in one barrel at Stuttgart, Ark, 2,768 *A quadrimaculatus* The number of imagoes in the Arkansas fields was somewhat greater than in the fields of Louisiana

SPECIES OF ANOPHELES FOUND IN THE RICE REGION

Table 1 shows that *A quadrimaculatus* is the prevailing species found in the imago stage, nearly 97 5 per cent of the imagoes caught in the rice region of Arkansas belonged to that species During the summer of 1920, in Arkansas, the proportion of *A. crucians* tended to increase as the season advanced In June and September, 1925, we made collections in the same region, and, in addition, we surveyed many thousands of *Anopheles* in their resting places; not one *A. crucians* was seen. Geiger, Purdy, and Tarbett (2) caught 19,238 *Anopheles* near Lonoke, Ark., all of which proved to be *A. quadrimaculatus*. Comparing our findings in 1920, in which over 800 *A. crucians* were caught, with our findings of 1925 and with those of Geiger, Purdy, and Tarbett, it would appear that in the same general area considerable variation in the proportion of *A crucians* may occur in different years

In the Louisiana rice fields the proportion of *A. crucians* is high; nearly half of the imagoes we took in the adult stage were of that species. In June, 1917, Geiger, Purdy, and Bates (3) found in the Gueydan district of Louisiana imagoes of only *A. crucians* and *A. punctipennis*, the *A crucians* being about twice as abundant as the *A.*, *punctipennis*. *A. quadrimaculatus* was first found by them in the latter part of June, and by July 10 this species superseded all others.

The high proportion of *A. crucians* in the Louisiana rice fields as compared with the Arkansas fields is striking. Breeding conditions in the rice fields of both regions are similar, except that a larger proportion of the Arkansas fields are irrigated by water from wells. The times of seeding and harvesting rice are nearly synchronous in the two States, and both States have an even, high summer temperature. In the Louisiana rice country the monthly mean temperatures for June, July, and August range from 79.9° to 82 8° F., and the annual mean temperature ranges from 67.4° to 69 1° In Arkansas the rice region has an annual mean temperature of 61 5° (Chambliss)

It has been alleged that the hydrogen-ion concentration of *Anopheles*-breeding waters may be a factor in determining the prevalence of certain species In the Louisiana rice fields we made 35 tests of the hydrogen-ion concentration in different years and at different seasons, and obtained a range of pH 6.0 to pH 8.6. Twenty-six of the 35 tests fell within the range of pH 7.8 to pH 8.2 A well supplying water for irrigation varied from pH 7.2 to pH 8.4, and water from an irrigation canal had a pH of 6.8

In the Arkansas rice fields we found a range of pH 6 8 to pH 9.2 Of a total of 15 tests (all made in June and September, 1925), we found 12 within the range of pH 7.2 to pH 8.4. Eight tests of wells supplying water for irrigation gave the narrow range of pH 7.2 to pH 7.4.

The hydrogen-ion concentration in the rice fields shows, then, a considerable range, depending in part on the distribution of masses of algæ, which tend to increase the alkalinity of the water; but the range is so similar in the rice fields of the two States as to make it unlikely that the greater prevalence of *A. crucians* in Louisiana is

due to any quality of the hydrogen-ion concentration of the water in which the *Anopheles* breed.

In Table 2 is shown the number of *Anopheles* bred out from larvæ or pupæ collected during 1923 and 1924 in the rice fields of Louisiana. It is seen that more than twice as many *A crucians* as *A quadrimaculatus* were bred out. It is interesting to compare this proportion with that of the percentage of *A crucians* caught in the imago stage, where this species comprised only 43 per cent of the adult *Anopheles* collected in the same region.

The discrepancy between these two percentages is not easy to explain. It is possible that the two species, *A. quadrimaculatus* and *A crucians*, prefer different daytime resting places, and that in our collections of imagoes, made for the most part in barns housing animals at night, we did not always include the preferred resting places of *A crucians* *A quadrimaculatus* often predominated in resting places immediately adjacent to rice fields where the larvæ and pupæ of *A crucians* were by far the more common of the two species

In addition to *A crucians* and *A quadrimaculatus*, a few *A. walkeri* were found Two *A walkeri* were bred out in the rice fields of Louisiana, and their imagoes were occasionally found in resting places near the rice fields We found but few *A punctipennis* as adults or larvæ During the summer of 1920 we collected many thousands of *A quadrimaculatus* in the rice region of Arkansas, but found only 10 *A. punctipennis*.

Culicine larvæ were plentiful in the rice fields and their imagoes often constituted a pest, especially in the Arkansas region. In the Louisiana and Arkansas regions, while the rice is being flooded, common species are *Psorophora columbiae* Dyar and Knab, and *Psorophora discolor* Coq., together with *Psorophora ciliata* Fab. Later, as grass and algæ increase in the rice fields, *Culex* (*Neoculex*) *testaceus* (=*territans*) Van der Wulp and *Culex* (*Choeroporpa*) *leprincei* Dyar and Knab are also found commonly with the larvæ of *Anopheles*.

THE MALARIA PARASITE AND SPLEEN INDEX IN THE PRAIRIE RICE REGIONS

Geiger, Purdy, and Bates (3) surveyed a population at Lonoke, Ark., during the month of January and found only 0.5 per cent infected with malaria parasites among 1,965 persons examined. In May they found in the same district 1.6 per cent infected among 2,162 examined. Children 1–10 years of age gave zero per cent in January and 1.9 in May. In the Gueydan district of Louisiana they made a survey in April and found but 1.1 per cent infected among 417 persons examined. Children 1–10 years old gave an index of 1.8 per cent. They found a malaria history rate of 29 per cent in the Lonoke population and exactly the same rate in the Gueydan group.

In our survey of the Louisiana rice region made some six years later than that of Geiger, Purdy, and Bates, we also found very low parasite rates. Our results for school children are shown in Table 3, which compares malaria indices of the rice country with those in surrounding regions not near rice fields.

TABLE 3.—*Parasite indices in Louisiana, 1923–1924 (school children)*

	Number of schools	Number of school examinations	Number children examined	Per cent positives
Group I. Schools in the immediate vicinity of rice fields.				
White	10	11	399	1.8
Colored	6	14	364	3.8
Total	16	25	763	2.8
Group II. Schools not in the vicinity of rice fields.				
White	11	16	499	2.8
Colored	14	20	568	5.1
Total	25	36	1,067	4.0
Grand total, groups I and II	41	61	1,830	3.5

Schools and school "examinations" are distinguished in Table 3, because in some cases a school was examined more than once, either in different years or in the spring and autumn of the same year. There are fewer repetitions of the examination of the same child than would be indicated by the ratio of schools to school examinations because there were frequent changes in the personnel of the schools. Practically all schools were rural, or situated in small towns. So far as we made any selection of schools for examination it was in the direction of those in the more malarious districts.

Table 3 shows clearly that the malaria parasite rate among school children of the Louisiana rice district is low, and somewhat lower than in schools in the surrounding country, where cane and cotton are the principal crops. Of the 61 school examinations made, about

one-half gave no positives at all—the proportion of negative school examinations being about the same in and out of the rice region.

Colored children gave higher indices than the white, and the autumn index was higher than that of the spring. Of 1,113 children of both races examined during the spring term, from January to May, inclusive, 3.0 per cent were found positive. Of 717 examined during the autumn term, all during September, October, and November, 4.1 per cent were found positive.

In addition to the school work, we determined the malaria parasite index of certain Louisiana plantations, lumber camps, and neighborhoods. Within the rice region, 4 of such surveys gave 3.2 per cent positive among 123 persons examined. Outside of the rice region, 15 surveys gave 6.8 per cent positive among 577 persons examined.

We also examined many blood specimens for the physicians of Crowley, La. During 1923 we obtained 88 positive specimens through this source, and in 1924 only 22. The percentage of positives among such examinations is of little significance because we dealt with a highly selected group; the fact that we found so few positives is noteworthy, however, since several physicians cooperated with us during the entire malaria season of two years.

In April, 1923, 190 spleen examinations were made of school children in Louisiana by Kenneth F. Maxcy, Passed Assistant Surgeon, United States Public Health Service. Only 3.6 per cent showed enlarged spleens. Examinations were made of the child in the standing position. Forty-two of the children examined were found in a school (Gueydan) located in the immediate vicinity of rice fields; all were negative. The remainder came from localities more or less remote from rice fields.

TABLE 4.—*Malaria parasite rate in certain rural schools in Arkansas*

With but few exceptions, our surveys of the Arkansas schools were made in September, October and November, months in which the malaria parasite rate is highest Table 4 shows definitely that the parasite rate of certain rural schools in the rice fields is low, and generally lower than that outside the rice region or at its borders. Especially remarkable is the low rate for schools Nos. 1, 2, and 3, surveyed during four successive years, in every case in September, October, or November The year rate of each of these three schools, as well as the aggregate for the four-year period, is low. Stukey school showed but one positive during the whole period. Spleen examinations were made of the boys of these three schools during the autumn of 1923 and 1924 by C P Coogle, Acting Assistant Surgeon, United States Public Health Service In the aggregate only 5 3 per cent of a total of 76 examined showed enlarged spleens

Schools Nos 1, 2, and 3 are situated in the very midst of the rice fields The children, all of the white race, live in houses for the most part good and situated in prosperous neighborhoods The population of the neighborhoods in which these schools are situated is relatively constant, showing less of the shifting so common among farmers of the renter class.

A group of town schools gave the following malaria parasite indices: 4.7 per cent positive among 86 colored children in two schools in the rice country; 11 6 per cent positive among 86 colored children in two schools at the edge of the rice country; 8.3 per cent postive among 169 white children in two schools also at the edge of the rice country; 0 per cent positive among 27 white children of a school not in the rice region

Certain house to house neighborhood surveys made in the Arkansas region may be compared with those of the schools We made these also in the summer and autumn, and in some of them we selected persons more likely to be infected The results are given in Table 5.

TABLE 5.—*Neighborhood surveys, Arkansas—Malaria parasite rate*

Total, white and colored		166	6 0	Total, white and colored		134	10 4

During portions of the summers of 1920 and 1922 we examined blood specimens for the physicians of Stuttgart, Ark. Most of the patients came from the rice region or the country immediately adjoining it. One hundred and one examinations gave 18 positives. This group, of course, was a highly selected one.

In sum, it is evident that malaria is present in the rice regions of both Louisiana and Arkansas, but that the rate is low, rather lower than in certain regions situated outside of the rice regions but in the same general neighborhood. Very low rates persist from year to year in certain neighborhoods situated in the midst of the rice fields where *Anopheles* swarm. The amount of malaria within the rice regions is doubtless increased by the presence of more highly infected communities at their borders.

In all blood examinations the slides were examined by one of us (Barber) personally, with the exception of the 1923 examination of the Arkansas schools, which was done by the United States Public Health Service laboratory at Memphis, under the direction of Dr. William Krauss. Thick films were employed in all specimens examined by ourselves.

THE TYPE OF MALARIA PARASITE FOUND IN THE RICE REGION OF LOUISIANA

The type of parasite found in the rice region of Louisiana is shown in Table 6, where data are arranged by months. We made but few examinations in the months of December and January, and obtained no positives during these months. One mixed case was found, but is not included in the table.

TABLE 6.—*Positive cases of malaria found in Louisiana, arranged by months and type of parasite*

Month	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	All months
Number of positives	6	4	4	16	10	10	23	27	22	11	133
Per cent of E-A	83.3	100.0	25.0	12.5	10.0	0	21.7	25.9	54.5	63.6	38.1

The number of cases shown in Table 6 is small, but sufficiently large to indicate clearly that the percentage of estivo-autumnal malaria falls to a minimum in June and July; then it rises rapidly, reaching its maximum in the late autumn and winter and in the early spring months. Barber and Mayne (4) have shown that a very similar curve of yearly incidence of the types of malaria parasite occurs generally in the Southern States, except that in the general series the minimum of the estivo-autumnal type occurs earlier in the season—April or May.

In the Arkansas rice region our surveys were made in late summer or in the autumn, when a high estivo-autumnal proportion would be expected. Of 46 positives obtained in the midst of the rice region, 50 per cent proved to be estivo-autumnal, of 76 obtained outside or at the borders of the rice country, 52.6 per cent were estivo-autumnal. In both groups positives obtained from negro cases showed a higher

percentage of estivo-autumnal than those from white. Of the total number of estivo-autumnal cases, about 39 per cent had crescents

It is stated that, with the decrease of malaria in the rice region of northern Italy, the estivo-autumnal type of parasite has become relatively rare (5) In our rice districts any amelioration in the number or severity of cases seems to have come about independently of any change in the type of parasite.

The effect on the malaria rate of the introduction of rice cultivation is hard to estimate since we lack trustworthy malaria surveys of the prairie regions prior to the beginning of rice culture The evidence of physicians in both regions is almost unanimous to the effect that there has been a decided reduction within the last 15 or 20 years in both the amount and the severity of the disease Blackwater fever and the more severe types of "swamp fever" have become almost extinct. Dr H. L Gardiner, health officer of Acadia Parish, a county situated in the midst of the Louisiana rice district, informed us that, during a tenure of office of six years, 1919 to 1924, inclusive, he had not signed a single death certificate for malaria A comparison of the parasite rates obtained by Geiger, Purdy, and Bates in 1917–18 with the rates obtained by us six years later indicate little more than the absence of a striking change in malaria during that period In schools Nos 1, 2, and 3, Table 4, one might deduce evidence of decrease in malaria, but the numbers are too small to show any significant change

THE RELATION OF RICE CULTIVATION AND MALARIA IN OTHER LOCALITIES

A relative immunity from malaria in the presence of numerous *Anopheles* bred in rice fields is not without parallel in this and other countries.

Herms (6) states that rice culture as practiced in California is responsible for vast hordes of *Anopheles*, but thus far there has been little or no increase in malaria as a consequence. Lenert (7) states that the more malarious portions of California are not found near the rice fields, but that there are few dwellings in their immediate vicinity.

Certain portions of northern Italy possibly furnish conditions more nearly parallel with those of our prairie rice fields—a temperate climate, intensive rice culture with irrigation, and the presence, within flight distance of dwellings, of abundant *Anopheles* known to be vectors of malaria The present condition of malaria in that region is described by Giardina, Novelli, Alessandrini, and Sampietro (5), and may be summed up as follows: Malaria in the valley of the Po, formerly severe and widely diffused, has decreased with the improvement in agriculture and with bettered social and sanitary conditions

of living. The reduction has been most marked within the last 30 years and is most pronounced where the cultivation of rice is most intense Benign tertian is the prevailing type of parasite found, and severe cases of malaria are rare. Estivo-autumnal, when it occurs, tends to run a mild course. Together with a reduction in the malaria rate, there has been a decrease in the death rate from all causes. In some localities of the rice regions the introduction of numerous cases infected during the World War caused an increase in the malaria rate But the rise was transient and the rate soon returned to normal. Apparently the "soil" had become unfavorable to the spread of the disease. *Anopheles* are present in enormous numbers. The anopheline species represented are *A maculipennis*, one of the chief malaria vectors of Europe, about 88–90 per cent; *A. superpictus*, about 7–10 per cent, *A pseudopictus*, 2–3 per cent; *A. bifurcatus*, rare.

Eugling (8) compares three villages in Macedonia, one in the swamps, one in a rice region, and one 1½ kilometers from rice fields The village in the swamp region shows the highest children's death rate, the other two showing a rate hardly one-half as great as that of the swamp dwellers. Spleen, parasite, and anemia rates were high in all three. The rice region was more favorable to the production of *Anopheles* than the swamps The author is of the opinion that the cultivation of rice has diminished malaria. With better economic conditions the people have better houses, better food, and better medical treatment, and are able to buy more quinine.

Nocht (9), in describing observations made in southern Europe during a recent journey, states that in Bulgaria malaria is no worse in rice-growing districts than in the truck-growing regions. In certain regions of Spain where rice cultivation is of ancient date and the inhabitants have become prosperous, malaria is insignificant in spite of abundant *Anopheles*; while in newly opened rice regions, where the people still have to contend with economic hardships, malaria is far more troublesome.

Certain rice-growing districts in the Orient also enjoy a relative freedom from malaria, but the species of *Anopheles* bred in them may not always be the most efficient vectors of malaria. Watson (10) states that on the coastal plains of Assam, where the *Anopheles* are *A. rossi*, *A. sinensis*, *A. kochi*, and *A. barbirostris*, the rice regions are generally healthful, whereas in the valleys where *A. minimus* and *A. maculatus* are also produced, they are generally unhealthful In certain regions of the Philippines, where the anopheline species are chiefly *A. rossi*, *A sinensis*, and *A. barbirostris*, Barber, Raquel, Guzman, and Rosa (11) found both spleen and parasite rates almost nil. Some rice regions of the Malay States also show a relatively low parasite rate. Walch (12), however, has described an epidemic of malaria in the rice fields of Java caused by *A. sinensis*. The *A.*

sinensis concerned in this epidemic was of the variety *vanus*, which may be a better vector than the type form

In Bengal, Bentley (14) describes an instance in which the decline in the irrigated culture of rice and jute has brought about a decrease in population and an increase in the malaria rate The building of embankments has prevented the annual inundations and the deposition of soil-enriching silt and has increased the swamp area The formation of swamps and of other waters lacking silt has increased the production of *Anopheles* also, so that conditions here are not exactly parallel with those of most rice regions, where mosquito production is usually augmented by irrigation But the impoverishment of the people through the decline in agriculture has doubtless been one factor in the increase in malaria

Kendrick (15) made a survey of 30,000 children in the rice-producing area of the Central Provinces of India In the open plains country he found an average spleen rate of only 4 3 per cent among 12,384 children. Areas with jungle and hill in excess and close to villages gave an average spleen rate of 70 5 per cent among 8,971 children An intermediate area comprising the edges of open plains near forest, jungle, or hill gave an average rate of 24 1 among 9,075 children Malaria, then, was not associated with the intensive cultivation of rice, but with certain topographical features The commonest *Anopheles* is *A. fuliginosus*, the next most common species, *A. culicifacies*, was considered by the author as the main carrier, since it corresponded in distribution with the malarial areas, and was the only one which showed sporozoites in the salivary glands

In other parts of India (5) the introduction of rice cultivation is said to have rendered a once salubrious region intensely malarious

In the United States rice was extensively cultivated along the Atlantic coast before the Civil War. According to Carter (16), malaria was formerly intense there and was commonly attributed to the "miasm" arising from the rice fields Gamble (17) states that in 1817 the city of Savannah took measures to abandon the wet culture of rice in the vicinity of the city. A report of a special committee of the council, in recommending such legislation, stated that previous to the introduction of wet culture the city had enjoyed a relative immunity from autumnal diseases. Dry culture was introduced and it was claimed that this measure reduced the proportion of persons dying from "autumnal diseases" from 1 in 11 of population during the first period of three years of wet culture to 1 in 35 during the second period of three years under dry culture. Apparently diseases other than malaria were included under "autumnal fevers."

In Italy also malaria was formerly so intense in the rice regions that legislation was introduced to limit rice cultivation to certain districts (5).

Provided an efficient vector of malaria is bred in sufficient numbers, it would seem that the mere introduction of rice culture can not be expected to reduce the malaria rate unless there is a concomitant betterment of the social and hygienic status of the people. It has been suggested, however, that certain biological factors having to do with the mosquito carrier may have contributed to the decrease in malaria Some of these factors will be considered.

Alessandrini (5) suggests the hypothesis that a mosquito species, normally an efficient vector of malaria parasites, may become less susceptible to infection through the favorable conditions under which the larvæ develop in the rice fields He compared a series of larvæ bred in the rice fields with those bred in swamps, selecting only larvæ about to pupate, in order to get a comparable size, and found that those bred in the fields are, on the average, measurably larger The more vigorous adults emerging from larvæ of the rice fields may, then, be less susceptible to malaria, following the analogy observed generally, that the weaker individuals are more susceptible to disease Little experimental evidence has thus far been adduced by the author in support of his hypothesis

In 1922, at Stuttgart, Ark , we attempted to determine by infection experiments whether mosquitoes bred in rice fields are susceptible to malaria infection. Our results are given in Table 7 The mosquitoes tested were all *A. quadrimaculatus*, collected in the imago stage from shelters in the midst of the rice region. They were taken at a time of drought when it was unlikely that any had been bred elsewhere than in the rice fields. All the human carriers on which the mosquitoes were fed harbored crescents; only that of lot No 5 had, in addition, any benign tertian gametocytes. We have included in the table only those mosquitoes which were known to have taken blood from the carrier. They were fed but once on the carriers.

TABLE 7 —*Infection experiments with rice-field-bred Anopheles, at Stuttgart, Ark.*

Lot No	Carrier No	Date of feeding, 1922	Number of crescents per 100 leucocytes	Number of mosquitoes dissected	Per cent of mosquitoes infected	Average number of oöcysts per gut in positives	Remarks
1	1	Aug 22	1	13	0 0	0 0	
2	1	Aug 23	1 5	12	58 3	2 5	
3	1	Aug 25	1	11	45 4	1 4	Patient had taken a total of about 70 grains quinine
4	1	Aug 26	0 8	14	64 3	5 3	Sporozoites in oocysts in gut
5	2	Sept 1	1	2	0 0	0 0	Crescents plus a few B T. gametocytes also
6	3	do	8 5	8	0 0	0 0	

14211°—26†——2

It is shown in Table 7 that three of six lots had a high percentage of infected mosquitoes The average numbers of oocysts is small, as is common where the percentage of gametocytes is low. Older oöcysts often showed "black spores" or other signs of degeneracy. We found sporozoites, in some cases apparently tending to degeneracy, in the oocysts of lot No. 5, but in no case did we find them in the salivary glands, although we dissected 12 with positive gut 10 or more days after feeding, including 9 positives dissected 12 to 15 days after feeding. Such degeneracy of oocysts and lack of sporozoites might be taken as evidence in support of the theory of Alessandrini, but these findings are by no means uncommon in mosquito infection experiments, whatever the breeding place of the mosquito

We did another series of mosquito infection experiments in Louisiana. Here the experiments were made for a different purpose, and it was less certain that the *Anopheles* used were actually bred in rice fields Mosquitoes were fed on two crescent carriers, one with 2.8 and the other with 3.5 crescents per 100 leucocytes. Twenty-one *A. quadrimaculatus* and one *A. crucians* were dissected, all proving negative. On October of the same year, when the rice-field-bred *Anopheles* had presumably disappeared, we obtained positive infection experiments with *A quadrimaculatus* caught in the adult stage, and with both benign tertian and estivo-autumnal parasites.

Our Stuttgart experiments show clearly that *A. quadrimaculatus* bred in rice fields may be infected with parasites of estivo-autumnal malaria; and we are inclined to doubt whether any species may be sufficiently modified by breeding in such a locality as to decrease greatly its power of transmitting malaria Rice fields exhibit an infinite variety of breeding places, of which not all are exceptionally favorable to anopheline larvæ, and myriads of adults come from waters very similar to those found in ponds or swamps. Further, in considering any biological factor we must give due weight to the evidence that malaria was formerly plentiful in certain rice-growing regions. The possible effect of food, aeration, or any characteristic of the breeding place on the susceptibility of the mosquito is a matter of importance and worthy of study; but a long and careful series of experiments would be required to give any definite information, since we have to do with complicated and highly variable conditions.

Rice fields are usually drained in September and the number of *Anopheles* is greatly diminished in early October; but it seems unlikely that the October diminution could have much influence on the malaria rate, since adults of *A. quadrimaculatus* are abundant from June to September, inclusive, a period comprising the warmer months of the year.

Domestic animals may possibly decrease the transmission of malaria by diverting from human beings mosquitoes in their search for blood, but it is doubtful whether this factor is of greater weight in the rice country than elsewhere. We have demonstrated that *Anopheles* in the rice country will bite human beings in a stable crowded with domestic animals (18), and the Italian authors above quoted (5) have made a similar observation in Italy. The malaria rate is higher in the Arkansas rice country than in that of Louisiana, although domestic animals in the Arkansas region are quite as numerous as in the Louisiana rice country, and better housed.

Longevity of the mosquito is presumably important in respect to the probablity of its transmitting malaria. In the rice country of Arkansas we (19) have demonstrated by staining methods that adult *Anopheles* may live in the open during midsummer and under natural conditions as long as 25 days.

It has been suggested that thick woods may promote the prevalence of malaria, possibly through affording favorable shelters for *Anopheles* Such woods are plentiful in both the Arkansas and the Louisiana rice regions Further, malaria may be very intense in a very thinly wooded country, as Calabria, in southern Italy. In the survey of malaria in rice fields described by Kendrick (15), nearness to jungle seemed to have promoted malaria, but here the jungle may have furnished a breeding place for the chief vector of malaria, *A. culicifacies*.

Purdy (20) describes the great variation in the anopheline output of different California rice fields, some of which produce practically no *Anopheles*. He believes that there is a probability that such lack of breeding in certain fields is due to the presence there of a heavy growth of a blue-green alga, *Tolypothrix tenuis*. He did not find this alga abundant in the rice fields of Arkansas or Louisiana, nor could we find any amount of it there.

Chara robbinsii is very abundant in the Louisiana rice fields, but does not appear to deter the production of *Anopheles* (21).

THE HUMAN FACTOR IN THE PREVALENCE OF MALARIA IN THE RICE REGIONS

The history of malaria in rice regions and the study of the present status of the disease lead one to ascribe the relative freedom from malaria in rice regions to human rather than to mosquito factors. Certain of the human factors as they exist in the prairie rice regions will be briefly considered.

In neither Arkansas nor Louisiana is much hand labor employed in the cultivation of rice. The greater part of the preparation of the soil and the seeding, irrigation, and harvesting is done by machinery. Some hand labor is employed in weeding, but the number of such

laborers is inconsiderable Negro laborers are employed in rice production, but the greater part of them live in towns and go out to their work in the fields. There is no large rural negro population such as is found on the cotton plantations of the Mississippi Delta. A large proportion of the owners of rice farms live on their own land and cultivate it themselves. There is no large class of "croppers" poorly housed, or of "bunk-house" labor in the prairie rice country, whose presence tends to favor the transmission and spread of malaria. We should be on our guard, however, against placing too much stress on the labor or any other single human factor in the prevention of malaria. In the rice country of northern Italy malaria is comparatively insignificant, although a large amount of transient hand labor is employed in weeding and other work. On the sugar plantations of Louisiana, where malaria is not usually severe, the labor, chiefly negro, is usually housed in unscreened cabins clustered around the sugar "centrals."

The quality of the dwellings in the prairie rice region is somewhat above the average found in cotton-growing territories. In the Arkansas region screening is almost universal, although many of the houses are imperfectly screened. In Louisiana, screening is alsocommon, although by no means universal. Many rural houses are wholly without this protection.

The use of quinine as a preventive by well persons is uncommon in the rice regions, as everywhere else in the country, and early treatment of cases is about as common there as in any well-to-do country The Italian authors above quoted (5) hold that quinine has been an important factor in the diminution of malaria in Italy—not through prophylaxis in the sense of immunizing the well but through the prompt use of the drug in treatment Quinine is abundantly and cheaply available to the laborers and they are accustomed to take it at the first appearance of malaise.

The population of the prairie rice regions of both Arkansas and Louisiana has within recent years shown a notable increase—a factor which would tend to decrease the malaria rate, but not necessarily the amount of malaria (22). In both districts, however, a large proportion of the increment in population has come from the Northern States or from other localities relatively free from malaria and is composed of people presumably susceptible to the disease; it is unlikely, therefore, that the relatively rapid increase in population has of itself greatly diminished the malaria rate.

In summing up the social and hygienic conditions in the rice regions it may fairly be stated that the conditions of living of the rural population are generally superior to those found in the rural regions of other parts of the Southern States.

MALARIA IN CERTAIN REGIONS NOT RICE-PRODUCING

In considering the factors which may have affected the malaria rate in the rice region, we should keep in mind the fact that there has been a marked diminution of malaria in other parts of the United States in the presence of numbers of *Anopheles* apparently adequate for the transmission of malaria. During 1923 and 1924 we made surveys comparing the prevalence of malaria in certain regions bordering the upper and lower portions of Bayou Teche in southwest Louisiana. The results of these surveys, which appear in Table 8, illustrate the fact that, of two regions, neither of which is near rice fields, but both abounding in *Anopheles*, one may exhibit a low malaria rate and the other a relatively high one. The upper Teche is mainly devoted to cotton growing and the lower to sugar-cane. In the lower region *Anopheles* breed in a series of more or less weedy lakes, and in both regions in the swamps bordering the bayou. All biological conditions which may affect the mosquito-breeding places—presence of woods or of domestic animals—are similar in the two regions In the upper region we found some groups of negro renters among whom the malaria rate was relatively high In the lower region most of the negro plantation workers live in cabins near the sugar factories.

TABLE 8.—*Parasite index of certain regions bordering the upper and lower portions of Bayou Teche in Louisiana*

	Number examined	Per cent positive		Number examined	Per cent positive
Upper Teche			Lower Teche:		
9 colored schools	271	8 1	3 colored schools	95	0.0
10 white schools	310	3 9	5 sugar plantations	179	1 1
6 neighborhood surveys	239	11 7	1 lumber camp	31	0 0
2 plantations	83	9.6	1 neighborhood survey	25	0.0
Total	903	7.8	Total	330	0.6

In southern Alabama also we found a region where the malaria rate was very low in spite of the presence of *Anopheles*, both *A. quadrimaculatus* and *A. crucians*, in numbers apparently fully adequate for malaria transmission.

In none of the regions we have described—the prairie rice country, the Alabama region, or the Teche regions—had there been any systematic attempt to control malaria.

METHODS OF CONTROL OF MALARIA IN RICE REGIONS

Geiger and Purdy (23) used sawdust soaked with fuel oil (about 3 gallons of oil to a bushel of sawdust) as a larvicide in some experimental plots of rice. The mixture when sown broadcast destroyed 85 per cent of the larvæ without injuring the rice.

We have found Paris green effective as a larvicide in rice fields provided the plants are not so tall and thick as to intercept too large a proportion of the dust. We treated an area of about 2,000 square meters with one-fourth pound of Paris green mixed with dust. The dust was thrown into the air and distributed by the wind. Over 90 per cent of the larvæ were destroyed by a single treatment. In a second tract, where the rice was about 30 inches tall, thick, and blossoming, we got much poorer results with a similar treatment.

King and Bradley (24) made use of an airplane in dusting a tract of flooded rice with Paris green Five pounds of Paris green mixed with 100 pounds of Tripoli earth were distributed over a tract of 7½ acres, where the plants were about 20 inches in height. The distribution of the dust was thorough, except that one edge of the field was missed on account of a strong wind "For the whole 'cut' an estimated mortality of 73 per cent resulted, but with the exception of the one edge practically 100 per cent of the large larvæ were destroyed as well as the majority of the small ones."

In their experiments, as well as in ours, it was found that the quantity of Paris green necessary to kill anopheline larvæ is not injurious to the rice plants.

It appears that Paris green might be a practical means of destroying anopheline larvæ in a small group of rice fields, but where many thousands of acres have to be treated, as is the case in rice regions of Louisiana and Arkansas, the use of any known larvicide would be impracticable on account of the expense.

Destruction of larvæ by intermittent drainage has been proposed. However, such drainage always leaves many puddles which would continue to breed *Anopheles*. Further, as pointed out by Geiger and Purdy, drainage in these level plains is likely merely to transfer the larvæ to another locality where they will continue their development within flight distance of dwellings.

There is no question that the presence of *Gambusia* or other top-feeding minnows will reduce the numbers of larvæ in rice fields. Geiger and Purdy (23) state that they reduced by 70 per cent the numbers of mosquito larvæ in an experimental plot by the introduction of top-feeding minnows. We have noted that where water is pumped from wells into a field unstocked with *Gambusia*, breeding may be very intense. In July, 1924, we had an opportunity of testing the efficiency of top-feeding minnows in certain plots of the rice experimental farm at Crowley, La. Into certain plots, fish were introduced freely; from others they were excluded by means of weirs or other devices. A very few fish may have entered into the "fish-free" plots, but their numbers were inconsiderable. The incidence of anopheline larvæ in the "fish-containing" and the "fish-free" plots was compared by dipping. Seven hundred and seventy-seven dips

in the fish-containing plots gave an average of 0 63 anopheline larvæ or pupæ per dip and in the fish-free plots 460 dips gave an average of 1 03 larvæ or pupæ per dip Pupæ were more numerous in the fish-free plots, the ratio of pupæ to total larvæ being 1:61 in the presence of the fish and 1:23 in the fish-free plots By way of comparison, the incidence of anopheline larvæ in certain ditches well stocked with *Gambusia* was compared with that in similar ditches immediately adjacent and wholly fish-free The former gave an average of 1 54 larvæ or pupæ per dip (98 dips) and the latter an average of 2.75 per dip (36 dips). In these ditches the culicine mosquitoes were almost wholly destroyed by the fish, being apparently more accessible to the minnows than the *Anopheles*.

It is clear from these observations that one can not depend on fish as a means of control of *Anopheles* in breeding areas so immense as those afforded by rice fields, because sufficient larvæ will escape the fish to produce large numbers of adults; but in regions where top-feeding minnows are lacking, it would be worth while to introduce them, since once established in canals or puddles they may persist from year to year, and at least somewhat lower the production of mosquitoes of all sorts.

The prohibition by legislation of the cultivation of rice within a certain distance of towns, a measure which has been carried out in Italy and in other regions, would not be practical in the prairie regions of the United States Geiger and Purdy, by means of stained mosquitoes, found that *A quadrimaculatus* will spread a distance of a mile or more from rice fields. Barber and Hayne (19), by means of a survey of daytime resting places, also found that *Anopheles* in effective numbers would spread a distance of a mile from the rice fields With towns and villages as thick as they are in some portions of Louisiana, therefore, a large proportion of the land, often little fit for anything but rice, would have to be abandoned or only partially used.

Screening and quinine, already mentioned, are certainly among the best of antimalaria measures in the rice country, as elsewhere. Education as regards the early and thorough treatment of attacks and as to the proper use of screens and other mechanical protection against *Anopheles*, is, of course, to be encouraged in every way. The elimination of carriers is important in any locality. Sixty-four persons in Louisiana whom we found infected with malaria parasites in 1923 were reexamined in 1924, and 28.1 per cent were again found positive. The general parasite index of the region during 1924, as indicated by the examination of 1,173 blood specimens of school children, was only 3.7 per cent.

Destruction of adult mosquitoes in houses may be an excellent measure, especially in case of an epidemic (12) (13). The disposition

of animals at strategic points in order to intercept or divert mosquito attacks, a measure practiced in Java (12), would hardly be practical in the prairie rice country of the United States With the immense numbers of *Anopheles* present even a human cordon seems unavailing. We found that large numbers of *A. quadrimaculatus* will penetrate a thickly populated town for a distance of at least a quarter of a mile.

DISCUSSION

In considering the effect of the cultivation of rice on malaria we must keep in mind the fact that the diminution of malaria or the maintenance of a comparatively low rate of the disease in spite of the presence of numerous *Anopheles* is a phenomenon by no means peculiar to the rice regions, although it is more striking there on account of the large numbers of *Anopheles* present. Further, in some parts of the world, high endemic and epidemic malaria may occur in rice regions, and the history of malaria in some rice regions now relatively exempt from the disease indicates that malaria was formerly intense in them. Apparently the amelioration in malaria prevalence in *Anopheles*-infested regions occurs only where improved agriculture or other social factor has brought about a general economic improvement in the condition of the people, an improvement which may have been the more rapid and complete where rice cultivation was introduced into swamps or into a prairie country little adapted to other sorts of crops It would seem that, with even a moderate betterment of social conditions, malaria in the United States tends to disappear or become relatively inconsiderable provided such improvement is general. Or, to state the proposition in another way, the maintenance of high endemic malaria requires a permanent reservoir of infection such as is furnished by a considerable body of people lacking proper housing, proper food, and adequate medical treatment. Now that pioneer conditions of life have in most parts of the country disappeared or have become modified, it is usually a certain type of renter class which provides the necessary reservoir of infection. It is well known that the impoverishment of a people or the introduction into it of unprotected temporary labor or soldiers may bring about an increase in malaria. The economic factor, then, is an important one and should receive due emphasis.

We do not wish to discourage the use of antimosquito measures or to regard such as unimportant. In regions where it is feasible to eliminate or greatly reduce *Anopheles*, such measures should be practiced; but where the *Anopheles* link in the chain of transmission of malaria is too strong to break, conditions are still far from discouraging, as is shown by the prairie rice regions of the United States where malaria remains at a comparatively low level without any conscious antimalaria work and in spite of an abundance of *Anopheles*. In

malaria work we must decide where to expend the greatest effort, a problem which must vary greatly in different regions.

It would seem that the study of regions of the type of the prairie rice country might afford malaria workers some hints as to means suitable for antimalaria work generally; but when we come to analyze the conditions found there, or try to evaluate the different factors comprised under the term "social improvement," it is difficult to determine which of them has had the most effect on malaria reduction. Screening and other precautions against mosquito bites, although by no means universally practiced in the rice regions of the United States, and employed but little in such regions of Italy, have doubtless been of direct influence against malaria. The use of quinine and medical treatment of malaria in general have probably improved Less direct measures, such as improvement in food, housing, hours of labor, water supply, and the like, have doubtless been of weight, since all tend to maintain a higher physical level and to prevent relapse of malaria attacks It would seem that nearly every phase of economic improvement has had some effect on the reduction of malaria

The work of the health officer in regions where the presence of numerous *Anopheles* is inevitable is, of course, limited. He may encourage screening and general betterment of tenant houses, a work which is already under way in certain States. He may make quinine as abundantly and cheaply available as possible Education of the people may encourage the proper use of screens and the early and thorough use of quinine. In certain malarious regions the inhabitants may be unduly disposed to await relief from the outside. In such regions the lesson of the prairie rice country may be applied and the people taught that a good part of the remedy lies in themselves, and that a betterment of conditions of living may bring about a considerable amelioration in malaria, even though mosquitoes are not immediately abolished.

Irrigated regions where a high anopheline rate is inevitable should be kept under hygienic supervision, even though the malaria rate be inconsiderable. Such regions should be regarded as being in a state of less stable equilibrium, and possible epidemics should be looked out for and detected as early as possible. But in the prairie rice regions of the southern United States conditions are now such that malaria should be no deterrent to the prospective immigrant that is willing to take comparatively simple precautions to protect himself. Among such precautions, screening, and proper treatment in case of an attack probably stand first.

SUMMARY

In the prairie rice region of the southern United States conditions favor a large production of *Anopheles* *A quadrimaculatus*, an efficient vector of malaria, is the predominant species, and *Anopheles* are very abundant from June to September, inclusive, a period of sufficiently high temperature to favor the transmission of malaria. There does not appear to be any biological factor having to do with the mosquito or its breeding places which would prevent these mosquitoes from being an efficient vector of malaria Malaria of both the estivo-autumnal and the benign tertian types is present in the rice region; but the rate is low and the malaria problem is not a serious one Attacks of malaria, when they occur, are usually comparatively mild, and deaths from the disease are rare The economic and hygienic status of the rural population in the rice region is relatively good, and this high general status is probably the most important factor in keeping the malaria rate at a comparatively low level. Conditions are such in the prairie rice regions that the fear of malaria should be no deterrent to immigration, provided simple precautions are taken by the immigrant, but, like any region heavily infested with *Anopheles*, the prairie rice country should be kept under hygienic supervision

ACKNOWLEDGMENT

We are indebted to Mr. Charles E. Chambliss, Associate Agronomist in charge of Rice Investigations, United States Bureau of Plant Industry, and to Mr. J. Mitchell Jenkins, Superintendent of the Rice Experiment Station, Crowley, La., for laboratory facilities and much other assistance.

PUBLIC HEALTH ENGINEERING ABSTRACTS

The 1926 Tourist Camp Survey.—Lewis S Finch, director, water and sewage department *Monthly Bulletin*, Indiana State Board of Health, vol 29, No 8, August, 1926, pp. 117–118. (Abstract by I. W. Mendelsohn.)

Supervision of tourist camps in Indiana was begun by the State board of health in 1923. At present there are about 325 such camps.

From May 20, 1926, to August 1, 1926, 227 camps were inspected. The inspector takes samples of all camp water supplies, investigates the methods of sewage and garbage disposal, and discusses unsatisfactory conditions with the owner or operator. When the laboratory examination of the water sample is completed, a report of the survey with recommendations is sent to the camp owner and to the health official in whose district the camp is located

The work in the past has been productive of good results, as shown in the following table:

Sanitary conditions of Indiana tourist camps inspected

Item	1923		1924		1925	
	Total number	Per cent good	Total number	Per cent good	Total number	Per cent good
Water supplies	99	74	174	74	184	81
Sewage disposal	97	15	181	48	186	84
Garbage disposal	93	16	174	71	192	82

Camp Sanitation is an Important Public Health Problem.—Charles G Cox, division of sanitation, New York State Department of Health, Albany, N Y *The Nation's Health*, vol. 8, No. 7, July 15, 1926, pp 459–461 (Abstract by Paul S. Fox)

Close cooperation between State divisions of sanitary engineering and local health officers is important, because most camp sanitation problems are of an engineering nature

Camp site—A camp is best located on western shore of stream or lake, since timbered section offers shade from hot afternoon sun. Soil should be porous and dry. Site should be free from mosquito breeding places

Water supply—Drinking water should be obtained from unpolluted springs or wells Larger camps sometimes maintain their own filter plants. Camps should be supplied with hypochlorite for emergency sterilization. Dual water supplies should not be allowed.

Sewage disposal—Flush toilets should be used whenever possible. Sanitary privies or chemical toilets may be used.

Garbage disposal.—Garbage should be disposed of daily by either burying or burning.

Milk supply.—Pasteurized milk should be provided, and, if possible, it should come from a tuberculin-tested herd. Milk should be stored in properly sterilized containers and kept at low temperatures.

The sanitary condition of camps depends not only upon the character of equipment but upon the degree of supervision by the camp authorities.

Administrative Phases of Stream-Pollution Control.—J E Monger, State director of health, Columbus, Ohio. *American Journal of Public Health*, vol. 16, No. 8, August, 1926, pp. 788–804. (Abstract by J. H. O'Neill.)

The effects of pollution may differ in various communities, but in general they may be classified somewhat as follows: (1) The menace of a contaminated public water supply; (2) the creation of nuisance otherwise affecting public health and comfort; (3) the damage to property with resulting depreciation of values; (4) the killing of fish and other natural stream life; (5) the damage to livestock; (6) the impairment of recreational facilities and destruction of bathing places; (7) the damage to public and private river and harbor improvements and navigation.

The general administrative features to be invoked in dealing with this problem are common to all States, and the necessity for meeting the problem is present in all of them. The underlying principles will vary but little; but variants, such as the quantity and quality of the various polluting agencies, the proximity of these points of discharge to water-supply intakes, and other important factors, render

a hard-and-fast consideration of administrative policies difficult The paper deals principally with the general underlying principles employed in Ohio

The Ohio law gives the State health department the same control over industrial wastes that it had over municipal wastes. It gives the public health council power to make regulations designed to meet the varying needs of different watersheds It limits the pollution problem to its present dimensions and permits the orderly consideration of each individual watershed according to the necessities of the case An important feature of the law is that permitting the coordination of municipal and industrial effort.

The things necessary to meet the problem of a future uncontaminated water supply are summarized as follows: Drive home its necessity and importance; develop a civic and industrial conscience that will not permit indiscriminate destruction of a great public asset; exercise a common sense degree of patience pending the development of economically possible methods of meeting the problem.

The question of the advisability of Federal legislation at the present time is a debatable one In dealing with interstate problems the joint actions of the respective States and the cooperation of Federal agencies is most important (Abstractor's note: The above paper is part of a symposium on the subject presented at the meeting of the American Public Health Association at Atlantic City, May 20, 1926. The discussion published with the papers contains much of interest)

Administration Problems in the Control of Pollution in Streams.—George W Fuller. *American Journal of Public Health,* vol. 16, No. 8, August 1926. pp. 777–781. (Abstract by J H. O'Neill.)

Although much progress has been made in the last 30 years, particularly with reference to the quality of public water supplies, the problem is far from complete solution. Gross nuisances in our streams abound and new ones come to affect those corrected. It is pointed out that the lack and failure of control of stream pollution can not be attributed to deficiencies in engineering knowledge or to the absence of legal and legislative measures for preventing pollution.

The answer to the question "Why is not stream pollution under better control?" is to be found in the shortcomings of present administrative facilities for carrying out suitable remedies designed to meet the demands of legislative acts, when interpreted in the light of the needs of the public from health and welfare standpoints Popular support and adequate funds are needed for effective work.

There are two types of administrative problems: One relating to the local or decentralized or internal problems for the particular locality in question, the other having to do with group, district,

regional, or Federal type of control. A discussion is given of each group.

A Model Milk Pasteurization Plant.—Anon. *The Medical Officer*, vol 36, No 2, July 10, 1926, pp 19–20 (Abstract by H A. Kroeze)

This article states that while Great Britain has been slow to adopt the methods of milk production and distribution which have been perfected in some of the cities of the United States, it is not yet generally realized what progress has been made in this direction during the last few years In London especially the great organization known as United Dairies (Ltd) has established standards of efficiency in the handling of milk supplies that would have been thought unattainable only a few years ago

On June 29 the new pasteurizing plant at Valley Farm, Streatham, was opened. Competent judges, both American and European, have declared this plant as second to none in either hemisphere. The article gives a brief description of the plant, and methods of receiving, pasteurizing, and bottling of the milk. Of particular interest are the methods used for washing bottles and cans—each utensil being washed for 20 minutes by an elaborate process—a description of which is given.

A brief note is made of the arrangements for the welfare of the staff, which are on a scale never before attempted in the dairy trade. These provide for rest rooms, two restaurants (men and women), bath rooms, drying rooms for roundsmen's clothes, laundry, and playing fields. There are also large and fully equipped stables with accommodation for 100 vans and horses.

DEATHS DURING WEEK ENDED OCTOBER 23, 1926

Summary of information received by telegraph from industrial insurance companies for week ended October 23, 1926, and corresponding week of 1925. (From the Weekly Health Index, October 27, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Oct. 23, 1926	Corresponding week, 1925
Policies in force	65, 641, 744	61, 606, 572
Number of death claims	11, 169	11, 350
Death claims per 1,000 policies in force, annual rate	8. 9	9. 6

Deaths from all causes in certain large cities of the United States during the week ended October 23, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925. (From the Weekly Health Index, October 27, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population

[2] Deaths under 1 year per 1,000 births Cities left blank are not in registration area for births

[3] Data for 63 cities

[4] Deaths for week ended Friday, Oct 22, 1926

[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31, Baltimore, 15, Birmingham, 39, Dallas, 15, Fort Worth, 14, Houston, 25, Indianapolis, 11, Kansas City, Kans, 14, Louisville, 17, Memphis, 38, Nashville, 30, New Orleans, 26, Norfolk, 38, Richmond, 32, and Washington, D C, 25.

Deaths from all causes in certain large cities of the United States during the week ended October 23, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, October 27, 1926, issued by the Bureau of the Census, Department of Commerce)—Continued

C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

PLAGUE ON VESSEL AT NEW ORLEANS

The Japanese steamship *Manila Maru* from Pacific ports, Buenos Aires, Argentina, and Rio de Janeiro and Santos, Brazil, arrived at New Orleans on October 24 with two human cases of bubonic plague. The patients were removed to the United States Marine Hospital, where one patient subsequently died. Diagnosis in both cases was confirmed clinically and bacteriologically. The steamer is now in process of complete deratization, which requires several fumigations during the discharge of cargo to prevent live rats from remaining in the cargo. Fumigations to date have yielded 130 rats, of which 6 of the species *alexandrinus* have been found to be infected. After complete discharge, the vessel will be given thorough fumigation throughout and will be surveyed by a service employee, an expert in ship rat-proofing, sent especially from New York for this purpose, in order to locate the breeding places of rats on the ship and permanently to eliminate all these in so far as possible. The vessel is bound for Galveston, Cristobal, and San Pedro.

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended October 16, 1926, 37 States reported 1,858 cases of diphtheria. For the week ended October 17, 1925, the same States reported 1,742 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,260,000, reported 960 cases of diphtheria for the week ended October 16, 1926. Last year for the corresponding week they reported 855 cases. The estimated expectancy for these cities was 1,133 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-five States reported 1,408 cases of measles for the week ended October 16, 1926, and 766 cases of this disease for the week ended October 17, 1925. One hundred cities reported 253 cases of measles for the week this year, and 386 cases last year.

Poliomyelitis.—The health officers of 37 States reported 66 cases of poliomyelitis for the week ended October 16, 1926. The same States reported 180 cases for the week ended October 17, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-six States—this year, 2,064 cases; last year, 1,563 cases; 100 cities—this year, 752 cases; last year, 692 cases; estimated expectancy, 639 cases.

Smallpox.—For the week ended October 16, 1926, 37 States reported 119 cases of smallpox. Last year for the corresponding week they reported 111 cases. One hundred cities reported smallpox for the week as follows: 1926, 23 cases; 1925, 45 cases; estimated expectancy,

22 cases. No deaths from smallpox were reported by these cities for the week this year

Typhoid fever—One thousand and thirty-seven cases of typhoid fever were reported for the week ended October 16, 1926, by 36 States. For the corresponding week of 1925, the same States reported 864 cases of this disease One hundred cities reported 184 cases of typhoid fever for the week this year and 198 cases for the corresponding week last year. The estimated expectancy for these cities was 177 cases

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,560,000, as follows: 1926, 475 deaths; 1925, 534 deaths.

City reports for week ended October 16, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Rabies (human): 1 case and 1 death at St Joseph, Mo

[2] Typhus fever 1 case at Montgomery, Ala , and 1 case at Los Angeles, Calif

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended October 16, 1926, compared with those for a like period ended October 17, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, September 12 to October 16, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Jeddah, Kamaran, Perim.
Iraq.—Basra.
Persia.—Mohammerah, Bender-Abbas, Bushire
British India.—Karachi, Chittagong, Cochin, Vizagapatam, Tuticorin, Negapatam.

[1] Public Health Reports, Sept. 10, 1926, p 1984

Ceylon.—Colombo
Federated Malay States.—Port Swettenham.
Straits Settlements.—Singapore, Penang
Dutch East Indies.—Batavia, Cheribon, Surabaya, Samarang, Palembang, Sabang, Makassar, Banjermasin, Tarakan, Padang, Balik-Papan, Samarinda, Menado
Sarawak.—Kuching.
British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.
Portuguese Timor.—Dilly
French Indo-China.—Saigon and Cholon, Turane, Haiphong.
China.—Hong-Kong
Formosa.—Keelung
Japan.—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki
Korea.—Chemulpo, Fusan
Manchuria.—Mukden, Changchun, Harbin, Antung.
Kwantung.—Port Arthur, Dairen
U S.S R.—Vladivostok

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island
New Guinea.—Port Moresby
New Britain Mandated Territory.—Rabaul
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea
Fiji.—Suva.
Hawaii.—Honolulu.
Society Islands.—Papeete

AFRICA

Egypt.—Port Said, Suez
Anglo-Egyptian Sudan.—Port Said, Suakin.
Eritrea.—Massaua
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Mogadiscio.
Kenya.—Mombasa
Zanzibar.—Zanzibar.
Tanganyika.—Dar-es-Salaam.
Seychelles.—Victoria.
Portuguese East Africa.—Mozambique, Beira, Lorenco-Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indies.—Pontianak.
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga
Madagascar.—Tamatave, Majunga.

ALGERIA

Plague—Algiers—September 23, 1926.—Information received under date of October 14, 1926, shows the occurrence of a case of plague at Algiers, Algeria, September 23, 1926.

CANADA

Communicable diseases—Week ended October 16, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended October 16, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				2				2
Influenza	12							12
Lethargic encephalitis				2				2
Poliomyelitis				8				8
Smallpox				3		1	6	10
Typhoid fever		5	10	20	7	2	4	48

CUBA

Malaria prevalence—Santiago—July-August, 1926.—On July 12, 1926, 75 cases of malaria were reported present at Santiago de Cuba. Malaria prevalence was continuously reported to October 16, 1926, with 20 cases present on that date. Population, 70,000.

Typhoid and other fevers—Water supply.—Typhoid fever and intestinal fevers were stated to be prevalent and the water supply and sanitary system inadequate.

EGYPT

Typhoid fever prevalence—Alexandria.—Typhoid fever prevalence was reported at Alexandria, Egypt, September 23, 1926. Previous reports show the occurrence of 55 cases of typhoid fever at Alexandria from July 1 to 29 and 128 cases with 10 deaths from July 30 to August 26, 1926.

HAITI

Disease prevalence—Port au Prince.—Disease prevalence has been reported at Port au Prince, Haiti, for the months of July, August, and September, 1926, as follows. Gastroenteritis continuously present and constituting the most important health problem of the community; tuberculosis and typhoid fever present with an unreported number of cases; malaria stated to be present in many sections of the Island. Population, 120,000.

MADAGASCAR

Plague—July, 1926—August 1–15, 1926.—Plague has been reported in the Island of Madagascar as follows: July 1–31, 1926—cases, 17; deaths, 16. The urban occurrence was: *Tamatave* (port) cases, 3; deaths, 3 (bubonic); *Tananarive* (interior)—cases, 4; deaths, 4 (pneumonic).

August 1–15, 1926 —Cases, 30; deaths, 25. The urban occurrence was as follows: *Majunga* (port)—cases, 14; deaths, 10; *Tamatave* (port)—cases, 3; deaths, 2 (bubonic). *Tananarive*—(interior) cases, 3; deaths, 3 (pneumonic, 2; septicemic, 1)

Further relative to plague at Majunga, Tamatave, and Tananarive.—On August 14, 1926, bubonic plague was declared epidemic at Majunga. This locality was stated to be the most important port on the west coast of Madagascar. At Tananarive from August 15 to 24, 1926, two deaths from plague in Europeans, members of the same family, were reported The last previous occurrence of plague in Europeans was stated to have been in the year 1924.

SALVADOR

Mortality—San Salvador—July, 1926 —During the month of July, 1926, 60 deaths from communicable diseases were reported at San Salvador, Republic of Salvador. Gastroenteritis caused 43 deaths, measles 6, tuberculosis 9, typhoid fever 2. (Population, 85,000)

Mortality—Malaria—Republic of Salvador.—During the period under report, 3,485 deaths were reported in the Republic of Salvador. The prevailing diseases were stated to be malaria and other tropical fevers. (Population, 1,600,000.)

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

The reports contained in the following tables must not be considered as complete or final as regards either the lists of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C. C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

VOL. 41 NOVEMBER 12, 1926 NO. 46

PAN AMERICAN CONFERENCE OF DIRECTORS OF HEALTH

In accordance with a recommendation of the Fifth International Conference of American Republics, which was held in Santiago, Chile, in 1923, the First Pan American Conference of National Directors of Public Health was convoked and the delegates met in Washington, September 27, 28, and 29, 1926

The inaugural session was held in the Hall of the Americas of the Pan American Union, where the Hon Joseph C Grew, Undersecretary of State, Dr. L S Rowe, Director General of the Pan American Union, and Surg Gen Hugh S. Cumming, Director of the Pan American Sanitary Bureau, made addresses of welcome These were appropriately answered by the delegates, in representation of their various countries

It is not possible to publish the full text of the welcoming addresses and the replies of the delegates at this time, but a complete report of the transactions of the conference will be published later (in Spanish), which will be available for distribution.

Among the most important results of the deliberations of the conference may be mentioned the creation of a permanent organization composed of the national directors of health of the respective countries affiliated with the Pan American Union, together with the officers of the Pan American Sanitary Bureau; and the work effected in the preparation of the program for the Eighth Pan American Sanitary Conference which will be held in Lima, Peru, from October 9 to 19, 1927

After the sessions of the conference, the delegates were welcomed to and attended many of the sessions of the Conference of the International Tuberculosis Union and of the National Tuberculosis Association of the United States. Later, some of the delegates went to New York, where they made trips of inspection to the United States quarantine and immigration stations, at Rosebank and Ellis Island.

Following is the official translation of the "Acta final" of the conference.

FIRST PAN AMERICAN CONFERENCE OF DIRECTORS OF PUBLIC HEALTH

WASHINGTON, D. C., U. S. A.

Summary of transactions

The inaugural session of the First Pan American Conference of National Directors of Health was convened in the building of the Pan American Union at Washington on September 27, 1926, the date set by the Pan American Sanitary Bureau in accordance with a resolution approved by the Fifth International Conference of American States.

The Surgeon General of the United States Public Health Service, Dr Hugh S. Cumming, presided over the session as provisional chairman

The Undersecretary of State of the United States, the Hon. Joseph C Grew, the Director General of the Pan American Union, Dr L S. Rowe, and Surg Gen. Hugh S. Cumming, Director of the Pan American Sanitary Bureau, welcomed the members of the conference, the delegates of each of the countries represented replying with appropriate speeches expressing their thanks. The conference considered and approved the regulations governing its sessions. At the same time, nominations were made for the offices of president, vice president, and secretary general of the conference, the following being unanimously elected: For president, Dr. Hugh S. Cumming; for vice president, Dr. Alfonso Pruneda, of Mexico; and for secretary general, Dr. Sebastián Lorente of Peru.

The following delegates of the countries represented and officers of the Pan American Sanitary Bureau were recognized as members of this conference:

Bolivia, Dr. Cleómedes Blanco Galindo and Dr. Manuel A. Villaroel; Brazil, Dr. Raul Leitão da Cunha; Chile, Dr. Lucas Sierra; Colombia, Dr. Pablo García Medina; Cuba, Dr. Fernando Rensoli, Dr. Mario G. Lebredo, and Dr. César Muxo; Dominican Republic, Dr. Ramón Báez, jr.; Ecuador, Dr. Pablo A. Suárez; Guatemala, Dr. José Azurdia; Haiti, Commander C. S. Butler and Mr. Raoul Lizaire; Honduras, Dr. Antonio Vidal M.; Mexico, Dr. Bernardo J. Gastélum; and Dr. Alfonso Bruneda, member of the Pan American Sanitary Bureau; Panama, Dr. Guillermo G. de Paredes, Paraguay, Dr. Andrés Gubetich; Peru, Dr. Sebastián Lorente; United States of America, Dr. Hugh S. Cumming, Dr. Samuel B. Grubbs, Dr. Bolívar J. Lloyd, Dr. Edward C. Ernst; and Venezuela, Dr. Carlos J. Bello.

In accordance with the respective provisions of the regulations, four committees were designated: (1) Committee on resolutions; (2) Committee on the Pan American Sanitary Code; (3) committee

on permanent organization; and (4) committee on sanitation and the administration of public health.

The committee on resolutions was composed of the following:

Dr Sebastián Lorente, of Peru, secretary general of the conference
Dr Raul Leitão da Cunha, of Brazil.
Dr Lucas Sierra, of Chile
Dr Pablo García Medina, of Colombia
Dr Andrés Gubetich, of Paraguay

The committee on the Pan American Sanitary Code was composed of the president, the secretary general of the conference, and the chief health officer of each country affiliated with the Pan American Union, and is charged with the duty of preparing and submitting to the Director of the Pan American Sanitary Bureau, not later than May 31, 1927, a report on the provisions of the Code.

The following delegates were chosen as members of the committee on permanent organization:

Dr. Sebastián Lorente, of Peru, secretary general of the conference
Dr Lucas Sierra, of Chile.
Dr Pablo García Medina, of Colombia
Dr Fernando Rensoli, of Cuba
Dr Andrés Gubetich, of Paraguay

The committee on sanitation and the administration of pubic health was composed of the delegate of highest rank from each country, or, if no distinction of rank existed, of the chief public health authority.

The conference considered, in its sessions of September 27, 28, and 29, all the matters and reports submitted. Dr. Sierra, of Chile, Dr. Lorente, of Peru; Dr. Vidal, of Honduras; D . Báez, of the Dominican Republic; Dr. Gubetich, of Paraguay; Dr. Suárez, of Ecuador, Dr. Bello, of Venezuela; Dr. Gastélum, of Mexico; Dr. Leitão da Cunha, of Brazil; Dr. Azurdia, of Guatemala; Dr. García Medina, of Colombia; Dr Blanco Galindo and Dr. Villaroel, of Bolivia; Dr. Rensoli, of Cuba; and Dr. Paredes, of Panama, outlined briefly the sanitary administrations of their respective countries. The propositions made during the period of the conference were submitted to the committee on resolutions.

At the meeting of September 29, the committee on resolutions presented to the conference its report on the matters which had been submitted for its study, and at the same session the conference approved the resolutions, recommendations, and measures given below:

The First Conference of National Directors of Health of the American Republics, meeting in the city of Washington, September

22. Organization in each country, in the respective departments of health, of a permanent commission for the study and eradication of malaria.

23. Organization of the study of climate and locality in relation to the epidemiology of disease

24. The conference recommends to the States of America which have not yet ratified the Sanitary Code approved at the Seventh Pan American Sanitary Conference, held in Habana in 1924, that they ratify this Code, making such reservations as they may deem necessary with respect to such articles as, for the time being, they may deem best not to accept.

25. To recommend to the governments the establishment of ministries of health, social welfare, and labor, where these do not already exist

26 A permanent organization is hereby effected, which shall be composed of the chief national public-health authorities of the countries affiliated with the Pan American Union, and also of the officers of the Pan American Sanitary Bureau.

27. To recommend that, in addition to the directors of public health of each country affiliated with the Pan American Union, the permanent organization should include the heads of the health services of the colonies or possessions in the American continent which may later become members of the Pan American Union

28. In view of the great educational value of motion pictures, the Pan American Sanitary Bureau is requested to undertake the production of films on subjects of hygiene and prophylaxis, and to supply the films in its possession, in turn, to the nations of the Pan American Union, for purposes of public-health education

29. The study and classification of rodent fleas by an expert entomologist in each country, and the forwarding of said data to the Pan American Sanitary Bureau. If there is no such expert available, the fleas shall be sent to the Sanitary Bureau, which shall undertake their study and classification.

30. The conference recommends to all governments that, in order that the Pan American Sanitary Bureau may more readily carry out the provisions contained in Article LVI of the Pan American Sanitary Code, they shall send to the Pan American Sanitary Bureau two copies of all official health publications, and, in addition, copies of all prevailing laws in each country bearing on health and sanitation.

31. The Conference of National Directors of Public Health shall meet every five years unless the Pan American Sanitary Bureau shall deem it expedient to convene such meeting at an earlier date.

32 A committee shall be named for the study of the measures adopted against the introduction of plague into the city of New York in order that its report may serve as a basis for the standardi-

zation of such procedures in all the countries of the Pan American Union. The committee shall be composed of Dr S B. Grubbs, Dr Lucas Sierra, and Dr Pablo Suárez

33. Recommendation is made to governments of countries where the cinchona tree grows to facilitate its cultivation and exploitation in order to be able to obtain quinine in quantity, quality, and at a price which may permit the intensification of the campaigns against malaria in the countr es of the Pan American Union.

34. The conference, before terminating its sessions, devoted a brief period of time to the memory of the great hygienist, Gen. William C Gorgas, whose labors for improvement in the hygiene of the American continent and of the world in general are worthy of the greatest admiration.

35. The conference also rendered grateful homage to the memory of the distinguished hygienists, Drs. Carlos J. Finlay and Henry R. Carter, to whom humanity owes invaluable services. This fact was communicated to the daughter of Doctor Carter and to Doctor Finlay's son.

To carry out these resolutions a committee was appointed, composed of Doctors Rensoli, of Cuba, Suárez, of Ecuador, Vidal, of Honduras, and Paredes, of Panama, who visited the widow of General Gorgas and the daughter of Doctor Carter, and also sent a telegram to Doctor Finlay's son in Cuba

36. A vote of thanks was tendered to Dr Hugh S. Cumming, Surgeon General of the United States Public Health Service, and Director of the Pan American Sanitary Bureau, to Dr. L S. Rowe, Director General of the Pan American Union, to Dr. Bolívar J. Lloyd, assistant to the Director of the Pan American Sanitary Bureau, to the members of the Pan American Sanitary Bureau and of the Pan American Union, and to the representatives of the American Government, for their efforts in the interest of this First Conference of National Directors of Public Health Services of the American Republics, and for its success.

(Signed) HUGH S. CUMMING,
President of the Conference.

(Signed) SEBASTIÁN LORENTE,
Secretary General of the Conference.

Report of Committee on Plague

The committee appointed by the First Pan American Conference of Directors of Health to formulate a program for the investigation of plague recommends that the Pan American Sanitary Bureau request each of its signatory powers to begin in one or more places, preferably ports, a plague survey of rats and fleas. It shall be the purpose of such surveys to more clearly define the factors of the spread of plague to the end that the degree of infectibility of a locality to plague may be determined as has been done in the instance of yellow fever through establishing the *stegomyia* index

(1) Live rats and other rodents are to be caught regularly each day throughout at least one continuous year

(2) Each rat is to be examined and classified and all ecto-parasites are to be collected, examined, and identified.

(3) Records are to be kept on standard blanks and all of the information called for on these blanks should be supplied in each instance. Other data called for on optional blanks may also be kept.

(4) In order that the classification of fleas may be uniform, specimens of each species are to be submitted to the expert designated by the Pan American Sanitary Bureau and confirmation of the classification made by such expert is to be considered as standard.

(5) Rodents, other than rats, and their ecto-parasites, are to be examined whenever possible, especially in those countries where they are domesticated.

It is believed that surveys as outlined above, if made by a considerable number of countries over a period of at least one year under identical circumstances, with records of results that are strictly comparable, will serve more definitely to fix upon the exact species and quantities of rodents and ecto-parasites that make possible the propagation of plague. In addition, other valuable data may be obtained which will accomplish the eradication of plague in a more efficient manner than is now possible.

NOTE.—Detailed instructions regarding the methods to be employed and copies of the blanks to be used are in preparation and will be distributed on request when available.

(Signed) Dr. LÚCAS SIERRA.
Dr. PABLO A. SUÁREZ.
S. B. GRUBBS.

THE NATIONAL LEPER HOME (MARINE HOSPITAL NO. 66)

Review of the More Important Activities During the Fiscal Year Ended June 30, 1926

By O E Denney, Surgeon (R) United States Public Health Service, Medical Officer in Charge

Since the United States Public Health Service assumed operation of this institution (formerly the Louisiana Leper Home) in 1921, 394 lepers have been hospitalized. In the fiscal year 1926, 62 lepers were admitted, and 25 absconded, 13 absconders returning for readmission.

Tabulation of the nativity of the patients in the hospital

Alabama	2	Bohemia	1
California	9	British Guiana	2
Florida	16	Canada	1
Georgia	2	Cape Verde Islands	1
Louisiana	94	Central America	1
Maryland	1	China	17

Alabama	1	Michigan	2
Arkansas	1	Montana	2
California	9	New Jersey	2
Florida	7	New York	4
Georgia	1	South Carolina	1
Illinois	2	Texas	5
Louisiana	20	Washington	1
Massachusetts	1		
Mississippi	1	Total	62
Missouri	2		

During the year three patients were paroled from the hospital, leprosy arrested and no longer a menace to the public health; another person voluntarily presented himself at the hospital for examination, having, at his own expense, crossed the continent believing, from newspaper readings, that he was suffering from leprosy; a careful examination revealed no symptoms of leprosy and he was refused admission to the hospital and returned to his former home. One leper was deported by the Bureau of Immigration

During the year, 94,359 hospital days were furnished. Twenty-nine lepers died, giving a mortality rate of 112 per 1,000 This mortality rate is slightly higher than normal, partly due to the fact that several lepers were admitted in terminal stages, almost moribund, and died soon after admission. The causes of death as confirmed by autopsy were as follows: Kidney malfunction, 8; cardio-vascular diseases, 6; tuberculosis, 5, pneumonia, 5; leprosy (apparently uncomplicated), 2, inoperable surgical conditions, 2; carcinoma, recurrent, 1.

Of significance with reference to the manner in which leprosy is contracted is the fact that in the hospital there are 6 veterans of the Spanish American War, 13 veterans of the World War, 3 veterans discharged from the military service because of disability, and 1 retired veteran—a total of 23 lepers who have had military service, some of whom had tropical service and probably contracted the disease while on foreign duty.

Seventy-five operations were performed during the year and 75,000 major and minor surgical dressings were made. Intravenous or intramuscular injections of mercurochrome, mercurophen, metaphen, bismuth, neo-salvarsan, and tryparsamide were continued in specific or experimental treatment.

A total of 37,902 physiotherapy treatments were given. Considerable improvement has been obtained in contractions or stiffness of joints and weaknesses of muscles, especially of the arms. Indurated areas have decreased, nerve pains have been relieved, and sensation in anesthetic areas of fingers and toes has returned in some cases Necrosis of bones has been arrested in some cases. Painful feet, flat feet, etc., have been relieved in many cases, and operations have resulted in marked benefit

The combination of contrast bath, radiant light, massage, and exercises has produced the most consistent results in the relief of contractions and the return of sensation in anesthetic areas. The ultra violet ray has proved very beneficial in nerve pains and ulcers.

Diathermy has not been used for a sufficient length of time to determine its exact value; but so far as it has been used it has become a helpful therapeutic measure apparently of great possibilities.

The most common affections of the eye have been superficial keratitis and iridocyclitis, the former leading ultimately to very poor vision through resulting opacities of the cornea and the latter to blindness through opacities of the lens The greater part of the current work with respect to the eye, has been devoted to staying the progress of these two affections, and a fair degree of success has been attained

With regard to neuropsychiatric work, 81 new cases of leprosy were examined and 150 reexaminations made of lepers previously studied. The neurological manifestations found in the 81 examined were of varied degrees of severity and consisted of sensory, motor, vasomotor, and trophic disturbances, five cases showing undoubted psychotic disturbances. One case of praecox type showed marked improvement during the last three months Two cases of amentia previously reported continue to show ravages of mental deterioration.

Treatment with chaulmoogra oil is being continued in a large group of patients, and, while no spectacular results have been obtained with either the oral administration of the crude oil or the intramuscular injection of its ethyl esters, it appears that definite improvement has followed in a sufficiently large percentage of cases to encourage the patients in the continuation of the treatment.

Impressed with the improvement in some cases following oral administration of large doses of the crude oil, an attempt is now being made to increase the dose tolerated by the stomach by the use of enteric capsules. Not enough data have been collected to warrant conclusions, but up to the present time nausea has not occurred in any of the few cases taking the oil in these capsules, notwithstanding the fact that much larger doses are being given than could be tolerated in ordinary capsules. How much, if any, of the oil is lost to the patient by passage of the unbroken capsule through the alimentary canal has not been determined, but reports indicate that this occurrence is infrequent.

Here, as in many other institutions for the treatment of leprosy, crude chaulmoogra oil is held in much esteem by many of the patients. Regret is frequently expressed that they can not tolerate larger doses. The enteric capsules are being tried in these cases in the hope that maximum doses can be given to a large number of patients and a fairer estimate obtained of the therapeutic value of the oil than has been previously possible on account of the limited tolerance so often exhibited. If nausea and vomiting can be eliminated, the oral route should permit of the administration of 60 or more times the amount of oil that it has been possible to give by the intramuscular injection of the ethyl esters.

Laboratory investigations have continued with one full-time medical officer and one assistant technician and with part time of a

second medical officer; 4,324 routine examinations were made, including autopsies and histologic examination of the tissues; 2,405 special examinations were made for research purposes

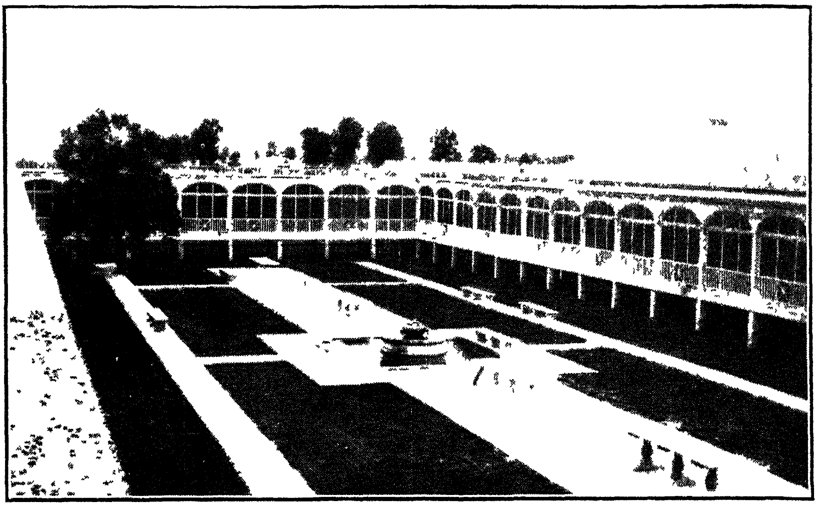
The Staff Journal Club, which was organized for the purpose of reviewing medical literature, has rearranged its meetings to conform to the Regulations requiring weekly staff meetings. At these meetings, abstracts of medical literature are presented by the members of the staff in rotation, case histories are read and discussed, and a member of the staff presents reports on original observations on leprosy.

During the year, 31 physicians, 56 nurses, and 60 medical students visited the hospital for the purpose of familiarizing themselves with leprosy. The Sixth District Dental Society held its quarterly meeting in the hospital in order that, at its scientific session, the dentists might be given a demonstration of the oral manifestations of leprosy. Sixty-five dentists attended the meeting.

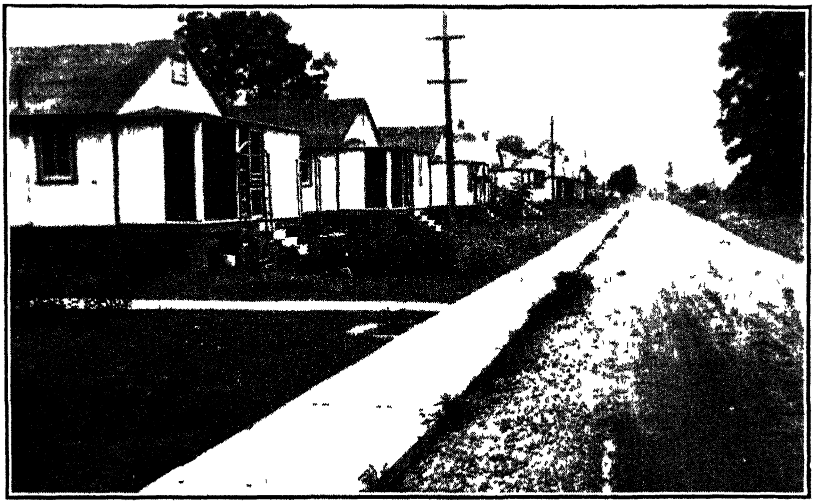
The library, operated by the patients, is becoming an ever-increasing source of information and entertainment. Magazines and newspapers are held in the library or lent on card until the issue is out of date and then are distributed upon application. During the year approximately 2,000 loans of current magazines were made and approximately 500 books of fiction, history, or current information were lent by the librarian.

Under the supervision of a resident representative of the Supervising Architect's office, there has been constructed a modern dairy barn having facilities for 80 milk cows, with calf pens, bull pens, maternity pens, feed-storage rooms, milk-cooling rooms, and showers and toilets for the attendants. The barn is equipped with overhead tracks for the movement of feed and for the removal of manure. A reinforced concrete septic tank has been built adjoining the dairy barn for the sanitary disposal of fluid excreta. Pending the availability of additional funds for the construction of other necessary dairy facilities, temporary structures have been erected to house feed-chopping machines, to store forage, etc. During the year the cattle herd was registered as nontuberculous as a result of repeated tests made under the direction of Federal and State authorities.

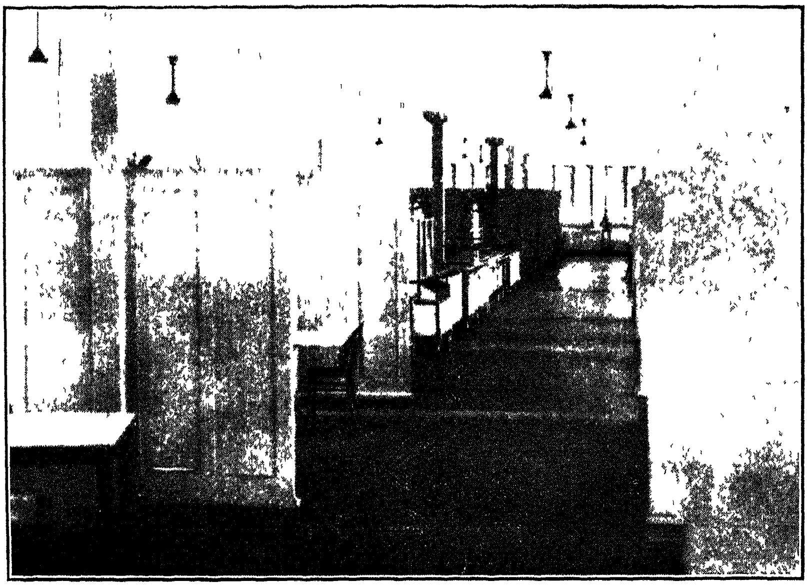
A formal tea garden, or patio, with a fountain, was constructed in the open rectangle immediately in front of the new kitchen and mess hall. This patio is being beautified with ornamental trees and shrubs and will add to the attractiveness of the mess hall. Similarly, a fountain has been constructed in the court immediately in front of the proposed new infirmary building, thereby promoting the continuous scheme for beautifying this particular spot prior to construction of the infirmary building.



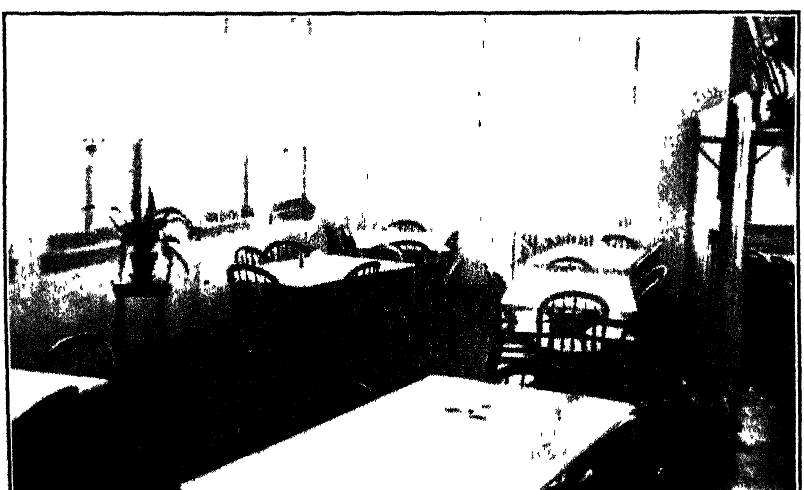
Quadrangle, facing patients' kitchen and mess hall



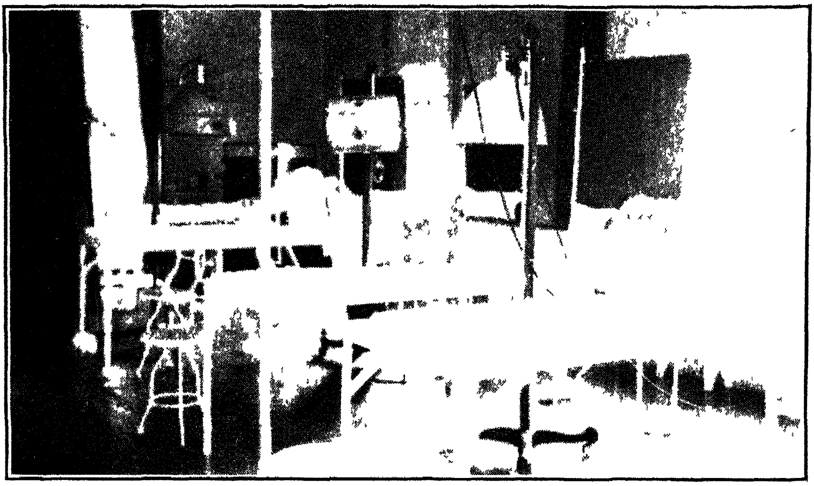
Concrete walks, serving also as covers for the conduits carrying the steam and water pipes



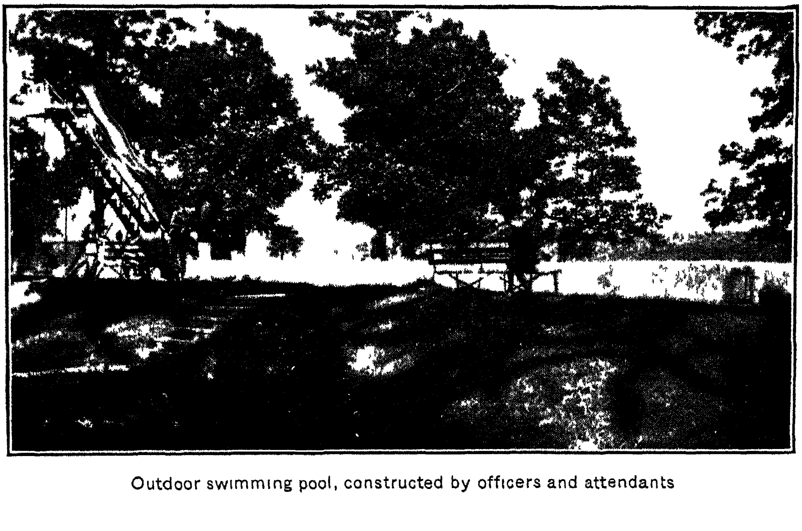
Patients' kitchen and mess hall—cafeteria arrangement



One of the cubicles in patients' mess hall These cubicles accommodate 24 patients

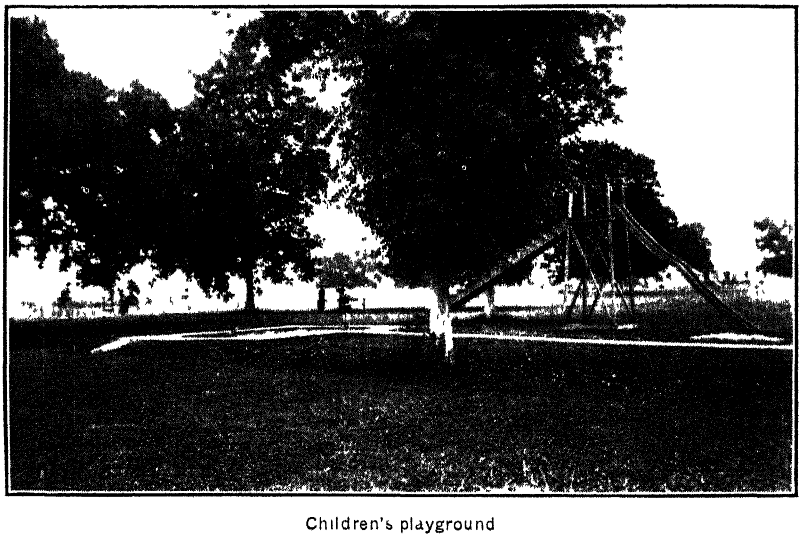


Physiotherapy department, showing electrotherapy wing



Outdoor swimming pool, constructed by officers and attendants

Rose garden and tea house



Children's playground

The crowded and very unsatisfactory dining-room quarters available for certain employees necessitated the construction of a temporary dining room adjoining the administration building for the use of negro employees This will serve its purpose satisfactorily until the completion of the authorized permanent addition to the administration building With surplus materials and station labor, a carpenter shop has been built, containing an electrically driven plane, a band saw, a shaper, a wood lathe, and other machinery. A blacksmith shop and a paint shop were similarly constructed

During the year this locality was visited by unprecedented rain storms, so that the portion of the reservation known as "The Lake," which had recently been cleared and put under cultivation, became flooded, owing to the fact that the drainage canals carrying off surplus rain water had become blocked on adjoining properties, and it became necessary to install compressed air lifts to pump the water from the lake. These air lifts became completely effective once the heavy, continuous rains had stopped, and the lake is again available for the cultivation of forage, although the crops already planted were lost

During the year all exposed water and steam lines serving the officers' and attendants' quarters were removed from their unsightly housing in wooden conduits above ground and were placed in concrete conduits, the tops of which serve as sidewalks, thus effectively dispensing with the large amount of waste energy due to radiation from the exposed steam and water lines and adding considerably to the neat appearance of the reservation.

During the year a corps of carpenters and painters has continued routine repair and maintenance of the 93 buildings on the reservation.

The approved scheme for beautification of the reservation has been followed. A number of shade trees, consisting of Lombardy poplars and American lindens and a variety of flowering shrubs have been planted, as well as a large number of palms, date, and *Washingtonia robusta.* A nursery of live oaks, the trees being now young saplings, will be available for transplanting at an early date; and these trees, although they will not furnish shade for the present generation, will no doubt afford refreshing physical comfort and esthetic pleasure in future years.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Plague in South Africa.—Anon. *Health*, Commonwealth of Australia, vol. 4, No. 4, July, 1926, pp. 127–128. (Abstract by J. L. Robertson.)

This article gives the history of plague in South Africa since its introduction during the Boer War, accompanied by a discussion of its perpetuation and dissemination by field rodents, the gerbille

serving as a main reservoir of infection, and the multimammate mouse acting as main intermediary between the gerbille and human habitation Infection flares up into epizootic prevalence among these animals in warm weather, coinciding with the seasonal prevalence of insects, especially fleas

Field surveys have been carried out in order to determine the extent of prevalence of infection and the distribution of veldt rodents liable to infection. A map accompanies the article showing the results of the survey effected up to the middle of 1925

Dr J A Mitchell, secretary of public health of the Union, emphasizes the fact that the balance of nature has been disturbed, due to destruction of natural enemies of the rodents by increased farming

That the risk of extension of infection to the domestic population of rail towns and ports is realized is evidenced by the plague conference which convened at Bloemfontein in November, 1924. A comprehensive plan of campaign was formulated, and urban local authorities have taken active measures against rats. In the meantime the survey and campaign against veldt rodents has been continued.

Paratyphoid Bacillus B. in Canned Ripe Olives.—W. R. Stokes. Jour. Am. Med. Assoc., 1925, vol 85, p. 1305 (1 ref) (Abstract by W. G. Savage.) From *Bulletin of Hygiene*, vol. 1, No. 2, February, 1926, p. 102.

"Two persons who ate the contents of a glass jar of ripe olives suffered, after an incubation period of about 24 hours, from fever, vomiting, and diarrhea, but with no symptoms of botulism. A guinea pig injected subcutaneously with 1 c. c. of the olive juice died after 24 hours, and from the spleen an organism culturally identical with the paratyphoid B. bacillus was isolated. This organism was agglutinated by paratyphoid B serum in a dilution of 1 : 800 (titre 1: 1,600). Stool examinations made after the patients had recovered failed to reveal any paratyphoid bacilli The colon bacillus and *B. proteus vulgaris* were isolated also from the juice and tissue of the ripe olives.

"(The facts suggest that a *salmonella* strain was responsible for the food-poisoning outbreak, but there is no evidence adduced that this was true *B. paratyphosus* B.)"

A Study of Milk Problems in Canada.—Dr. M. M. Seymour. *The Public Health Journal*, vol. 17, No. 6, June, 1926, pp. 295–301; No. 7, July, 1926, pp 353–358; No. 8, August, 1926, pp 394-404. (See Pub. Health Rep., July 16, 1926, p. 1477) (Abstract by R. E. Tarbett.)

The second installment of the report continues with statement from the various health departments as to the various causes giving them the greatest trouble in properly controlling the milk supplies.

The situation regarding Pasteurization is covered briefly, Quebec, Vancouver, and Victoria being the only large cities not favoring Pasteurization The balance of the second installment of the report is taken up with suggestions by various health officers as to educational methods

The third installment takes up the question of Pasteurization and tuberculin tests The standard definition for Pasteurization recommended by the committee is as follows: "Pasteurized milk is milk which has been heated to a temperature of not less than 142° F, and not more than 145° F., held at such temperature for not less than 30 minutes and then immediately cooled to a temperature of 50° F., and held at or below this temperature until delivered to the customer." Control of Pasteurization plants is discussed. Because of the use of inferior equipment and lack of knowledge as to operation, four suggestions are made relative to control, particularly in reference to new plants: (1) That a prospective plant furnish satisfactory proof of its ability properly to finance a plant, (2) that operators be required to have experience and be licensed; (3) that plants be licensed and required to pass a two or three months' probationary period, (4) that failure to comply with milk regulations would cause a cancellation of the license. Municipal Pasteurizing plants are suggested and compared with municipal water plants. Pasteurization of milk on the farm, while generally impracticable, might be possible with some of the larger dairies.

The necessity for having all milk cattle tuberculin tested is discussed. The means available for the testing of cows, Federal, provincial, and local, are outlined and discussed. Owing to inadequate appropriations, the proper inspection and laboratory control is generally not adequate.

Suggested essentials for a minimum standard for conditions under which milk is produced are given. It is pointed out that standardization and legislation can not be carried too far, and that officials should be given some opportunity to exercise their common sense.

Bombay Corporation Waterworks—Some Trouble over Rapid Filtration Plant.—Anon. *The All-India Local and Municipal Self-Government Gazette*, vol. 13, No. 1, July, 1926, pp. 28–32. (Abstract by E. C. Sullivan.)

This article is concerned with the failure of the contractors for a filtering plant at Powai Lake to construct a plant which would give the guaranteed quality of effluent within the limits of expenditure guaranteed by the contractors. Although the contractors were granted a period of several months to operate and improve the plant so as to obtain an effluent of desired quality, these efforts resulted in failure and the contractors have been called upon to withdraw from

the contract, in order that the work of completing the plant may be entrusted to other parties.

The quality of effluent which was guaranteed in the contract was as follows: (*a*) The filtered effluent shall not contain more than 100 total colonies per c. c. agar count; (*b*) absence of lactose fermenters in 50 c. c.; (*c*) absence of *B. coli* (Houston's) in 50 c. c.; (*d*) absence of free ammonia; (*e*) albuminoid ammonia not to exceed 0.1 part per million; (*f*) absence of free residual chlorine before entering the main after chlorine treatment; (*g*) freedom from taste and odor when heated to 37° C.; (*h*) removal of 100 per cent of suspended matter, (*i*) clarity to be such that a platinum wire $\frac{1}{25}$ inch diameter shall be discernible 6 feet beneath the surface at midday; and (*j*) it shall have no acid reaction under any circumstances and shall not contain more than one part per 100,000 alkalinity ($CaCO_3$).

The limits of consumption to produce an effluent of this quality must be guaranteed not to exceed (1) in the case of wash water, 1 per cent of quantity of water filtered; (2) in the case of alum 0 75 grains per gallon of water filtered; and (3) in the case of chlorine 15 pounds of bleach (30 per cent chlorine) per million gallons of water filtered.

Soil Acidity and Survival of Hookworm Larvae.—A critical commentary by L Fabian Hirst. *Indian Medical Gazette*, vol. 61, No. 1, January, 1926, pp. 14–17. (Abstract by D. L. Augustine.)

The author calls attention to the fact that his use of the term "hookworm larvae" in a former paper (Investigation on the Epidemiology of Hookworm Disease in Colombo. Part I: On the isolation and identification of infective nematode larvae. Part II: Observations on the Viability of Hookworm Larvae. *Ceylon Jour. Science*, Section D, Vol I, pp. 1–15) includes the whole history of the larvae from its emergence from the ovum to its death or penetration through the skin of man It is emphasized that in their brief cultural stage the larvae are especially vulnerable to physical agencies, such as high acidity, while the mature larvae are highly resistant to the action of a variety of disinfectants and other physical agencies generally harmful to living protoplasm.

The author states that well-grown infective larvae can probably live up to six months under average tropical conditions and possibly much longer under specially favorable circumstances. Such statements are misleading and carry with them the idea that all of a given number of infective hookworm larvae live for that length of time. It has been demonstrated repeatedly that only a very small percentage of them ever have a life span greater than two or three months under natural conditions, and that the majority of them perish within a month after the deposition of the stool containing the ova.

Soil Acidity and Survival of Hookworm Larvae.—A reply to Doctor Hirst's critical commentary, by Asa C Chandler *Indian Medical Gazette*, vol 61, No. 1, January, 1926, pp 17–18. (Abstract by D L Augustine)

The difficulty of determining the effect of soil acidity as a single factor in the development of hookworm larvae is discussed The author has observed that infective larvae do develop in considerable numbers in acid soils, he having isolated over 1,500 from a pint of Assam soil with a pH of 5 5. All these larvae appeared healthy and were well supplied with nutritional granules.

Incidence of Hookworm Disease in Mexico.—(Incidencia de la Uncinariasis en Mexico) Andrew J Warren and Henry P Carr Editorial, *Cultura*, Mexico, 1925, pp. 1–84 (Abstract by M. A. Barber)

In this work the authors take into account the degree as well as the extent of hookworm infestation They make use of the well-known relation existing between the number of hookworm eggs found in a unit amount of feces and the number of worms harbored by the individual. On this basis the severity of hookworm prevalence is mapped out for the different regions of Mexico, and determined for groups of different age, sex, and occupation The region of greatest infestation in Mexico lies in a zone of heavy rainfall lying more or less parallel with the Gulf and extending, approximately, from Yucatan to the State of Tamulipas. *Necator americanus* is the prevailing species of hookworm, comprising 92.3 per cent of the total number determined: *Ankylostoma duodenale* included but 7.7 per cent.

The article includes many tables, maps, and charts, as well as full descriptions of the climatology of the regions surveyed and of the technique employed. This short review can give but an inadequate estimate of the extent and value of this piece of work.

Notes on the Effect of Burial of Infective Hookworm Larvae.—W. W. Cort. *Jour. Parasit* 1925, vol. 12, pp. 33–38 (4 refs). Abstract by J. F. C. H., *Bulletin of Hygiene*, vol 1, No 4, April, 1926, p. 305.

"The author describes preliminary experiments undertaken with a view to determining the movements and fate of buried hookworm larvae. In general his results confirm the views of Payne, that conditions associated with the movement of ground water have a more important bearing upon upward migration than has the actual degree of moisture or dryness."

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended October 23, 1926, 37 States reported 2,119 cases of diphtheria. For the week ended October 24, 1925, the same States reported 1,938 cases of this disease. Ninety-seven cities, situated in all parts of the country and having an aggregate population of more than 29,600,000, reported 1,160 cases of diphtheria for the week ended October 23, 1926. Last year for the corresponding week they reported 902 cases. The estimated expectancy for these cities was 1,172 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-five States reported 1,825 cases of measles for the week ended October 23, 1926, and 999 cases of this disease for the week ended October 24, 1925. Ninety-seven cities reported 275 cases of measles for the week this year, and 517 cases last year.

Poliomyelitis.—The health officers of 37 States reported 70 cases of poliomyelitis for the week ended October 23, 1926. The same States reported 172 cases for the week ended October 24, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 2,121 cases; last year, 1,881 cases; 97 cities—this year, 867 cases; last year, 690 cases; estimated expectancy, 682 cases.

Smallpox.—For the week ended October 23, 1926, 37 States reported 220 cases of smallpox. Last year for the corresponding week they reported 128 cases. Ninety-seven cities reported smallpox for the week as follows: 1926, 18 cases; 1925, 40 cases; estimated expectancy, 29 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Eight hundred and fifty-six cases of typhoid fever were reported for the week ended October 23, 1926, by 36 States. For the corresponding week of 1925 the same States reported 907 cases of this disease. Ninety-seven cities reported 146 cases of typhoid fever for the week this year and 185 cases for the corresponding week last year. The estimated expectancy for these cities was 151 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 92 cities, with a population of more than 29,200,000, as follows: 1926, 515 deaths; 1925, 528 deaths.

City reports for week ended October 23, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

[1] Rabies, (human) 1 case and 1 death at Scranton, Pa. [2] Dengue, 3 cases at Charleston, S. C.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended October 23, 1926, compared with those for a like period ended October 24, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more

than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, September 19 to October 23, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Aden, Jeddah, Kamaran, Perim

Iraq.—Basrah.

Persia.—Mohammerah, Bender-Abbas, Bushire.

British India.—Karachi, Chittagong, Cochin, Vizagapatam, Tuticorin, Negapatam.

Federated Malay States.—Port Swettenham.

Straits Settlements.—Singapore, Penang.

Dutch East Indies.—Batavia, Cheribon, Surabaya, Samarang, Sabang, Makassar, Banjermasin, Tarakan, Padang, Balik-Papan, Samarinda, Pontianak.

Sarawak.—Kuching.

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.

Portuguese Timor.—Dilly.

French Indo-China.—Saigon and Cholon, Turane, Haiphong.

China.—Hongkong.

Formosa.—Keelung.

Japan.—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Shimonoseki.

Korea.—Chemulpo, Fusan.

Manchuria.—Mukden, Changchun, Harbin, Antung.

Kwantung.—Port Arthur, Dairen.

U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island
New Guinea—Port Moresby
New Britain Mandated Territory—Rabaul
New Zealand—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia—Noumea.
Fiji.—Suva.
Hawaii—Honolulu
Society Islands—Papeete

AFRICA

Egypt—Alexandria, Port Said, Suez
Anglo-Egyptian Sudan—Port Sudan, Suakin.
Eritrea—Massaua
French Somaliland—Jibuti
British Somaliland—Berbera
Italian Somaliland.—Mogadiscio.
Kenya.—Mombasa
Zanzibar—Zanzibar
Tanganyika—Dar-es-Salaam
Seychelles—Victoria.
Portuguese East Africa—Mozambique, Beira, Lorenco Marques
Union of South Africa—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indies—Palembang, Menado
Philippine Islands—Manila, Iloilo, Jolo, Cebu, Zamboanga
Madagascar—Tamatave, Majunga.

CANADA

Communicable diseases—Week ended October 23, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in six Provinces of Canada for the week ended October 23, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Total
Cerebrospinal meningitis			1				1
Influenza	14				1		15
Poliomyelitis		1		1			2
Smallpox				2		2	4
Typhoid fever			8	15	1	1	25

EGYPT

Plague—Western Desert Province—October 11–12, 1926.—Seven cases of plague were reported on October 11 and 12, 1926, in the vicinity of Sidi Barani, Western Desert Province, Egypt. Of these, four were bubonic in type, and three, with fatal termination, were septicemic. Plague was reported at Sidi Barani, September 3–9, 1926, with 12 cases.[1]

[1] Public Health Reports, Oct. 22, 1926, p. 2448

FINLAND

Communicable diseases—July, 1926.—During the month of July, 1926, communicable diseases were reported in the Republic of Finland, as follows.

Disease	Cases	Disease	Cases
Diphtheria	40	Paratyphoid fever	98
Dysentery	1	Scarlet fever	62
Lethargic encephalitis	1	Typhoid fever	50

Population, 3,469,402

HAWAII TERRITORY

Plague—Honokaa Village—October 6, 1926.—A fatal case of plague was reported October 6, 1926, at Honokaa Village, Island of Hawaii.

MALTA

Communicable diseases—September, 1926.—During the month of September 1926, communicable diseases were reported in the Island of Malta as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	8	Penumonia	3
Diphtheria	8	Puerperal infection	3
Erysipelas	5	Scarlet fever	1
Influenza	2	Trachoma	104
Malaria	5	Tuberculosis	22
Malta fever	78	Typhoid fever	50
Measles	12	Whooping cough	11

Population, civil, estimated, 223,088.

PERU

Plague—September, 1926.—During the month of September, 1926, plague was reported in Peru with 45 cases and 36 deaths, occurring in four Departments as compared with 21 cases with 9 deaths occurring in two Provinces during the previous month.[1] The occurrence was reported by departments as follows: *Junin*—Cases, 21; deaths, 20, occurring in one province and one locality. *Lambayeque*—one case. *Libertad*—Cases, 3; deaths, 1. *Lima*—Cases, 20; deaths, 15, of which 1 case with 1 death occurred at the city of Lima and 3 cases with 2 deaths in the vicinity on country estates. In the Departments of Ancash and Cajamarca plague was stated to have been present during the period under report.

[1] Public Health Reports, Oct. 15, 1926, p. 2370.

SPAIN

Mortality from communicable diseases—Madrid—September, 1926.—During the month of September, 1926, mortality from communicable diseases was reported as follows: Diphtheria, deaths, 6, measles, 3; scarlet fever, 13; tuberculosis, all forms, 132; typhoid fever, 15. The total number of deaths from all causes during the period under report was 998. Population, estimated, 766,552.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain. (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests

ORGANIZATION OF THE HEALTH PROGRAM OF A UNIVERSITY

By D F SMILEY, M D, Medical Adviser, Cornell University

Just as in the whole field of education, so in the special field of health education, there has been in recent years a marked change in the objectives Health has been redefined as "the quality of life that renders the individual fit to live most and to serve best," [1] and the aims of health education in the primary and secondary schools have been stated in the following terms: [2]

1 To instruct children and youth so that they may conserve and improve their own health

2 To establish in them the habits and principles of living which, throughout their school life and in later years, will assure that abundant vigor and vitality which provide the basis for the greatest possible happiness and service in personal, family, and community life

3 To influence parents and other adults, through the health education program for children, to better habits and attitudes, so that the school may become an effective agency for the promotion of the social aspects of health education in the family and community as well as in the school itself

4 To improve the individual and community life of the future; to insure a better second generation, and a still better third generation, a healthier and fitter nation and race.

A health-educational program is in operation in most of our urban schools, and even at this early date results are becoming quite evident [3] The next step in the development of the health-educational program is undoubtedly to be taken in the colleges and universities of the country. A preliminary survey of existing conditions has already been made and is shortly to be published,[4] and on the basis of those facts a comprehensive program is to be launched. The urgent question of the next few years in our college and university health circles is to be: How can we best organize our institution for health purposes? As a contribution to the solution of that trying problem I am herewith presenting suggestions based largely on Cornell University's experience in the field of health education.

[2] Report of Joint Committee on Health Problems in Education. By T D Wood, New York City, 1924

[3] For the last 3 years each entering class at Cornell University has shown progressively fewer physical defects and faulty health habits than the preceding class.

[4] Report of President's Committee of Fifty on College Hygiene By Thomas A Storey, College of the City of New York, New York City

I. AN ANALYSIS OF THE HEALTH NEEDS OF THE AVERAGE COLLEGE STUDENT

1. Healthful living conditions.
   - Good food at reasonable prices.
   - Sanitary water and milk supply.
   - Clean dining rooms and food handlers.
   - Healthful study rooms and classrooms.
2. Adequate health service.
   - Health advice
   - Infirmary services.
   - Medical examination service and laboratory service.
   - Communicable-disease control.
3. Well-adjusted activities
   - Congenial studies.
   - Suitable physical exercise
   - Wholesome recreation and sociability.
   - Thoughtful religious study and discussion.
4. Effective health instruction.
   - General biology.
   - Human anatomy.
   - Human physiology.
   - General bacteriology.
   - Personal hygiene.
   - Sanitation.
   - Public health.

II. RESPONSIBILITIES OF VARIOUS DEPARTMENTS FOR MEETING THE HEALTH NEEDS OF THE STUDENT

The health needs of the student are found to involve not only the university health service but the department of physical education, the departments of biology, bacteriology, anatomy, physiology, sanitary chemistry, dairy industry, sanitary engineering, the department of administration, the University Christian Association, the University Union or Social Center, and the various college orientation courses. And if we consider the ramification of one small part of the field of hygiene, i. e., sex hygiene, we find the following possibilities suggested by the American Social Hygiene Association and the Interfraternity Council:[5]

Sex and reproduction and their impulses and implications are not, as we have allowed ourselves to conceive them, isolated and distinct phases of life They are normal and integral parts of complete life, and furthermore, they irradiate into and profoundly modify all the rest of life that is worth while. For these reasons the educational treatment of these factors should not be unnecessarily

[5] An appeal for the greatest personal and social health for students. Report of the Committee on Social Hygiene of the Interfraternity Conference, 120 Broadway, New York City, 1922

separate from other phases of education, but wherever possible should be imbedded quite naturally and for the most part inconspicuously in all the physical, intellectual, emotional, esthetic, social, and moral education and training the youth receives

For similar reasons sex education should not be partial—that is, exclusively physical or emotional or religious—but it should represent a fair synthesis of all the interests and points of view which contribute vitally to ideas, motives, and conduct in respect to sex This synthesis must include the facts of the underlying sciences, as biology, physiology, psychology, hygiene, and pathology, and, no less, the idealism of the esthetic, social, and religious cultures, and equally the practical training and inspiration of everyday conduct and relations A sound or workable philosophy and practice of sex life can not be had if it ignores any one of these aspects

As a corollary of the above, the general program of the effective educational institution must be on an adequate hygienic basis throughout—in administration, in curriculum, in "activities," and in its social life.

Apparently, then, the health-educational responsibilities are widespread throughout the departments of the university.

III THE ORGANIZATION OF THE UNIVERSITY TO MEET ITS HEALTH EDUCATIONAL RESPONSIBILITIES

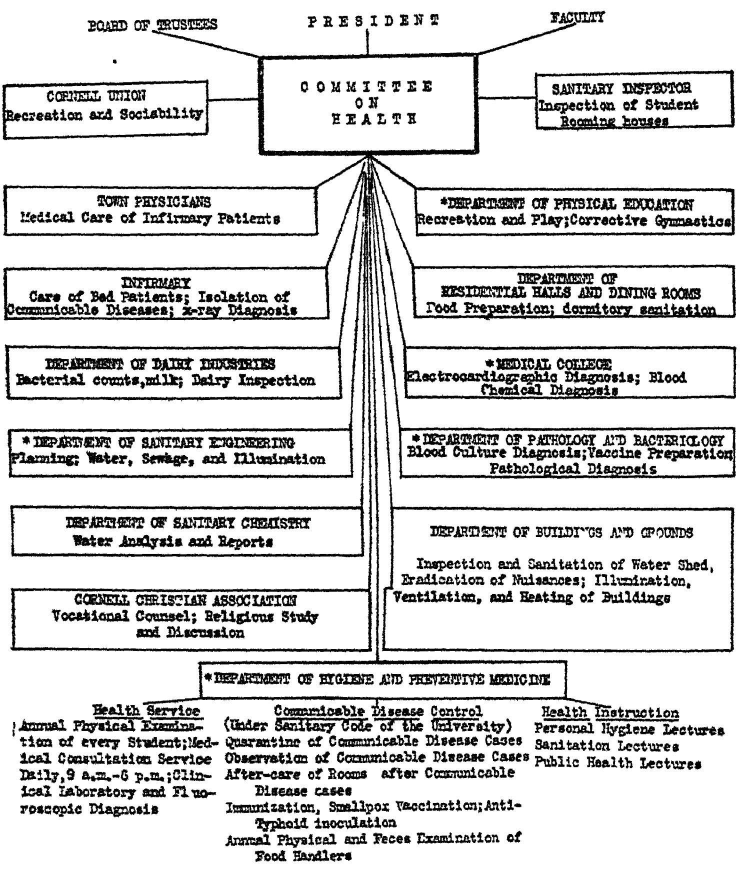
In the recent beginnings of health education in the universities of the country we have had examples of health education combined with physiology,[6] with biology, with physical education,[7] with bacteriology—largely as a matter of expediency and for the purpose of utilizing for the new health work the preexisting machinery most suited to the task. In many instances the scheme has been so effective as to result in a permanent organization In some quarters, however, the organization problem has been attacked from the opposite point of view; an attempt has been made to magnify the health interests and centralize under one head all of the health educational activities. Thus we have departments of student health representing the combined fields of health service, hygiene teaching, environmental sanitation, physical education, and intercollegiate athletics.[8] But even in the most pretentious departments of health there are some of the student's health needs still to be ministered to outside the realm of that department, and this raises the general question of whether it is worth while disrupting any of the old schemes of organization and subordinating any of the older departments for the purpose of attempting the impossible, i. e , having *all* of the health educational work centralized under one head in a university department of health.

When the opportunity for health educational expansion came, through the Interdepartmental Social Hygiene Board support at Cornell in 1919, it seemed wiser to charge one department, that of

[6] Vassar
[7] Princeton, McGill, Smith, Rochester.
[8] University of Michigan, Stanford University

the medical adviser (which had been responsible for physical examinations, health advice, and communicable disease control since 1911), with the added responsibility of hygiene instruction,[9] and then seek the cooperation of related departments through the organization of a faculty committee on health and a faculty committee on instruction in hygiene and preventive medicine, rather than through the actual consolidation of departments.

HEALTH OF THE STUDENT BODY AND SANITATION OF THE UNIVERSITY COMMUNITY



*Department represented in Committee on Health

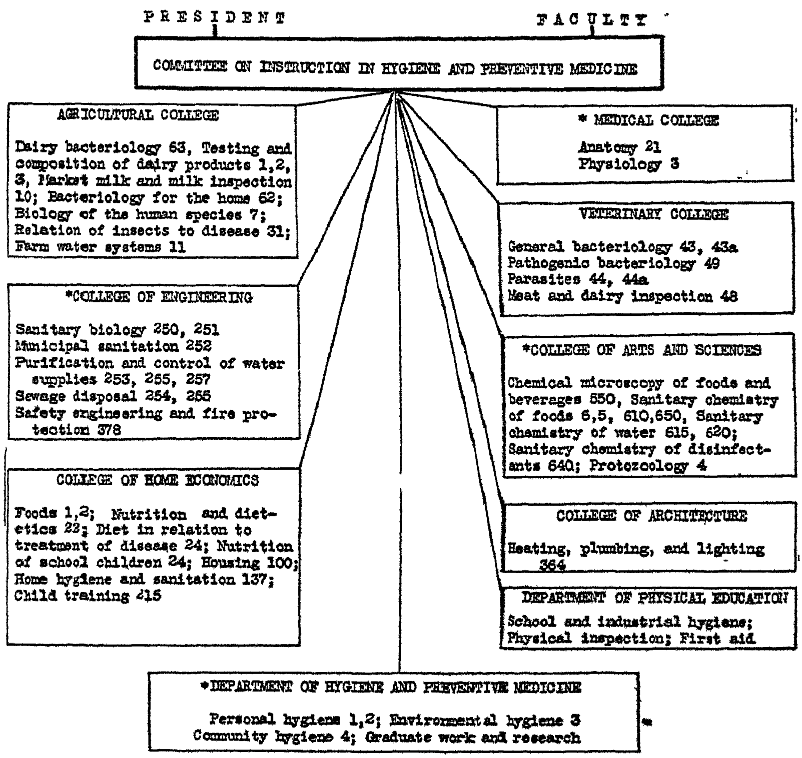
IV. THE CORRELATION OF VARIOUS DEPARTMENTS FOR HEALTH EDUCATION

Under this scheme the president of the university appoints each year from the various departments related to health five members of the committee on health, which committee constitutes the central

[9] Though this was first done in 1919, hygiene had been taught at Cornell either in the department of zoology or in the department of physical education since the founding of the university in 1868

authority in health matters and acts on all questions of policy in health affairs.[10] This insures that the various departments represented on the committee become conversant with the health problems facing the whole university. It also insures to the university the advantage of the consensus of opinion on important health questions of the departments concerned. The executive officer of this committee is the university health officer, in whom is vested the committee's authority for the purpose of administering the university

INSTRUCTION IN HEALTH AND PREVENTIVE MEDICINE AT CORNELL



*Department or college represented on Committee on Instruction in Hygiene and Preventive Medicine

sanitary code. The chart on page 2634 shows the scheme for correlation of health activities through this committee.

The committee on instruction in hygiene and preventive medicine is composed of four faculty members appointed by the president from departments related, always, however, including the dean of the university faculty. This insures faculty interest and cooperation in health education throughout the university without any reorgan-

[10] This faculty committee is usually identical with the trustee's committee on health, and it therefore carries the authority of the faculty and board of trustees

ization or subordination of departments already existing. It also administers the university requirement for four terms of hygiene instruction for each student. The scheme for correlation through this committee is shown in the chart on page 2635

Under such a system the health educational work of a university can be markedly developed and expanded; each aspect of the work, however, being developed in the department peculiarly adapted to that purpose, and the department of health itself remaining free from any suspicion of being desirous of dominating other fields, such as physiology, bacteriology, physical education, or organized athletics, with the health interest To be sure it is extremely important that the health interest be developed and stressed in the work of these related departments, but it is not entirely clear that in such departments health interests should supersede vocational or scientific investigative interests, or that health values should be more sought in physical education and athletics than such moral values as courage, fairness, etc.

V. THE DEVELOPMENT OF THE HEALTH EDUCATIONAL PROGRAM IN THE CORNELL UNIVERSITY DEPARTMENT OF HEALTH

The development of the health educational program in the university department of health we have found at Cornell to be almost entirely a job for physicians, not nurses—for young physicians, not retired practitioners—for physicians interested in health education and preventive medicine rather than specialists or those interested primarily in therapy. We have found that full-time physicians are preferable to part time, that men physicians are preferable for men and women physicians for women, that regular professorial ratings in terms of instructorships, assistant professorships, and professorships are preferable to other ratings, and that a schedule permitting each man to distribute his energy over the five fields of physical examination, medical consultation, communicable-disease control, instruction in hygiene and preventive medicine, and research, was preferable to directing his energy to any one field alone Our salary range for graduate physicians has been from $2,250 to $4,000 per nine-month school year, and there is no doubt that this level will have to be raised if we are going to continue to attract and hold the type of worker demanded. The hours of routine work have been six a day, leaving some time for research work or special follow-up work on the cases found in our examinations. On this basis we have found that we need at least one physician to every 500 students; and if the mental hygiene problems of the student body are to receive adequate attention, the proportion of doctors must of necessity in the future be considerably increased.

The work of the department of hygiene can be conveniently divided and described under the five headings—health examination, medical consultation, communicable-disease control, health education, research

Health examinations—Every undergraduate and every entering graduate student is required to have an annual physical examination. The examination which we have adopted as our standard procedure takes about 40 minutes for entering students and 30 minutes for old students, and is completed entirely, with the exception of the urine examination, by one physician For statistical accuracy the group method of examination is far preferable, but we have found that an examination has much more health value if the history, record of health habits, and physical findings are all at once in the mind of the examiner and he is able to devote his entire attention to the health problems of that one individual for half an hour and attempt to convince him of the importance of rectifying the remediable defects or faulty health habits found With such a system we, of course, make no attempt to complete our examinations during one period in the fall, but simply schedule our examinations one per office hour per doctor right through the year and thus complete the examination of the 4,800 undergraduates and entering graduates between the 1st of October and the 1st of June The appointments for these examinations are made at the beginning of the first term by all entering students and sophomores, at the beginning of the second term by all juniors and seniors. Athletes are examined first of all and given their athletic number or rejected from athletics early in the fall. No athlete is permitted to represent the university on an athletic team without having qualified for and procured an athletic number from the medical adviser's office. Recruits for the university reserve officers' training corps are accepted or rejected according to Army regulations at the time of their regularly appointed health examination. We therefore duplicate no examinations and give no special examinations of any kind—our only examination being our regular annual physical examination.

This plan is open to the objection that an entering student might go on undetected until almost midyear with communicable disease, but as a matter of fact we are more troubled by the acute infectious diseases occurring after Christmas and Easter vacations than by those occurring after the summer vacation, and it is questionable whether it would ever be worth while to examine the whole student body for communicable disease immediately after each vacation or to rush the examination of all students in the fall in order to pick up a little earlier the occasional case of tuberculosis or syphilis present in the entering class. A full-time force also demands a full-time examining schedule.

Inspection of the examination and history forms as found below (the forms for women students differ slightly) reveals certain inadequacies in the routine examination made necessary by the short time provided for examination; but provision can usually be made for a rectal, blood, eye ground or fluoroscopic examination if the history or physical findings indicate the necessity of such special examination. Serious organic disorders like chronic cardiac valvular disease, nephritis, or tuberculosis are found in a very small number of students—rarely more than 2 per cent; the majority of our findings are defects in posture, defects in vision, nasal obstruction, acne, malnutrition, infected tonsils, faulty habits of sleep, exercise, use of stimulants, etc. Our entering students have averaged 2½ of these remediable defects or faulty health habits per student for the past five years (though each succeeding entering class appears to have remedied slightly more of its defects before college entrance, and the urban group appear to have remedied their defects somewhat more than the rural group).[11]

Follow-up studies on the 150 to 200 albuminuria cases, 60 to 100 glycosuria cases, 50 to 100 chronic chest cases, etc., are made by calling in the student at intervals by letter. Among these cases we rarely find more than 2 actual cases of nephritis, 2 cases of true diabetes, 25 cases of definite tuberculosis (out of which, perhaps, 3 to 5 are active and forced to leave school and seek sanitarium treatment), and 50 actual cases of chronic cardiac valvular disease.

In our physical examinations we plan on devoting about two-thirds of our time to detecting defects and faulty health habits and one-third to convincing the student as to the necessity of remedying the condition found; thus one-third of the physical examination time is devoted to pointed personal health instruction This also gives an opportunity for discussion of sex-hygiene topics, though we raise this question ourselves only in the examination of freshmen. The encouraging fact in this whole field is that more than 94 per cent of the abnormal conditions found can be remedied or improved.

Medical consultation service—We have found that, in health as well as in other fields, "a stitch in time saves nine." Our medical offices are open daily from 9 a. m. to 6 p m., not to set fractures, nor to refract eyes, nor to give time-consuming treatments, but to give medical advice for any physical condition deviating even ever so slightly from the normal. This advice may be in the form of a suggestion that a specialist be consulted. or that diet or habits of life be somewhat altered, or that certain lines of simple medication be followed, or that the student go to the infirmary for bed care; but in each consultation the final consideration is, How can we

[11] D. F. Smiley: Health Inventory of Rural and Urban Students The Nation's Health, Vol. VIII, No. 1, January, 1926.

prevent a recurrence of the disabling condition? That this service is appreciated is evidenced by the fact that we carry on about 25,000 of these voluntary consultations per year, an average of 5 for each student in the university. Of these consultations, about 4,000 are for "colds" or their complications, about 750 for digestive disorder, about 650 for eyestrain, about 550 for indefinite headache or fatigue, about 250 for constipation, about 250 for furuncle, about 250 for dysmenorrhea; no other illness provides more than 200 cases a year. The fact that such large numbers of cases of digestive disorder, eyestrain, constipation, and furuncle occur year by year is a challenge to our health educative forces; the fact that "colds" and dysmenorrhea are still so common is a challenge to our health research forces.

The free use of the university infirmary in the case of any student needing bed care is one of the most valuable preventive factors in our health program. It is simply assumed that, since each student has paid his $5 infirmary fee each term, he is entitled to infirmary care whenever he is sick enough to be in bed. The only check needed against abuse of the privilege of infirmary care is the provision that, while there, each student must be under the daily care of his private physician, whom he chooses from the practicing physicians of the city. The efficacy of this system is to some degree attested by the fact that, of the 658 cases of influenza occurring during the past month of March, practically all were seen early, put to bed immediately in the infirmary, and permitted to leave only when they were safely convalescent. This meant sometimes caring for 140 to 150 patients a day in the infirmary; but it unquestionably aided in keeping the complications with pneumonia down to six cases—a figure less than 1 per cent of the total influenza cases.

Recommendations for excuse from class because of illness are recognized by the various college administrative offices only as they come from the medical adviser's office. Recommendations from town physicians and out of town physicians are brought to the medical adviser's office and filed and official recommendations issued. No official recommendation for excuse from classes is issued by the medical advisers at a period later than 48 hours after the resumption of classes, and no recommendation is made unless the student presents definite signs of illness or a certificate of illness from a physician. Thus we maintain a fairly complete morbidity record for the student body and prevent students from staying at home ill and returning to classes while still infectious. During the past year 1.28 per cent of the 4,570,533 school hours available to the 4,897 undergraduate students was lost as the result of illness. The lost time of instruction hours among the 1,173 women students was 1.8 per cent, and among the 3,724 men students was 1.1 per cent.

Communicable disease control.—The control of communicable disease in a college community is somewhat simpler than in a primary or secondary school because of the larger number of immunes. As a rule, for instance, we find that 90 per cent of our entering students have had measles and about 50 per cent have had mumps, whooping cough, and chickenpox. Therefore, in the construction of our university sanitary code we felt it safe to waive isolation of all contacts and substituted instead (in the case of the nonimmunes) a system of observation at the medical adviser's office at one or two day intervals throughout the incubation period of the disease in question. Immediate isolation of the patient in the contagious ward of the infirmary for a period extending from a week in case of measles to a month in scarlet fever is of course demanded. A satisfactory certificate of vaccination against smallpox is a requirement for matriculation. Such a certificate is deemed satisfactory only as it records a positive reaction (vaccinia, vaccinoid, or immune reaction) within five years, or three unsuccessful attempts within the same period. Tuberculosis cases showing tubercle bacilli in the sputum are not permitted to attend classes unless they furnish the medical adviser (who is also the university health officer) with satisfactory evidence that their care of secretions and their mode of life are such as to preclude danger of spread to others. Cases of gonorrhea (rarely more than eight a year) are not permitted to attend classes until treatment has been instituted and until they have a permit to return from the medical adviser Cases of syphilis (rarely more than three to five a year) are not permitted to attend classes until treatment has been instituted and there are no open lesions on skin or mucous membrane and until they have a permit to return from the medical adviser.

Synopses of this code are posted in all university buildings and dormitories and distributed to the various fraternities and rooming houses, and cordial cooperation of the student body is the general rule. As a result, we rarely see more than 40 cases a year of any one of these reportable diseases, though each year we expect an outcropping of one or several of these diseases after the Easter and Christmas recesses. The amount of time put into this system of control by the medical staff is rather large; we often call in and observe 700 to 800 contacts of various diseases in the course of the year. But among that group of contacts we will usually detect 10 to 20 secondary cases, and we therefore feel that the time spent in observing contacts is well spent, provided the contacts are carefully selected.

Though this system never entirely prevents the occurrence of these infectious diseases of childhood, it enables us (judging by the experience of the past six years) to keep them in hand, the number of cases rarely exceeding 75 a year. In regard to influenza, "colds," and conjunctivitis, however, we feel very much less optimistic.

Health instruction.—Just what a college student should know about health is a question which, Dr. Livingston Farrand, president of the university, attempted to summarize in the following terms: [12]

1 He should have a knowledge of the physiological basis for sound health habits, such as regular and sufficient hours of sleep, right posture, suitable exercise, and proper elimination.

2. He should know the types, amounts, and proportions of the various food elements essential to the proper nurture of his body

3 He should have an acquaintance with the principles of normal mental action and the conditions underlying the more common variations from normal state of mind

4 He should have a general understanding of the sex instinct—its stages of development, its normal expression, and the values and penalties attaching to it

5. He should have a knowledge of the factors determining infection and resistance and the principles of artificial immunization in the case of certain of the common infectious diseases

6 He should have enough knowledge of the causes and prevention of the degenerative diseases to offer a prospect of passing through middle life without a breakdown.

7 He should know, and therefore be armed against, health hazards lurking in the environment, such as polluted water and milk supply, congestion in housing, poisonous dusts of certain industries, infected soil, etc

8 He should appreciate the necessity for frequent medical and dental examination.

9. He should have an intelligent basis for choosing wisely his medical and dental advisers, and for realizing that the modern practice of medicine is grounded on science and not on mystery, fancy, and tradition.

10 He should have a knowledge of the important health problems facing the community, of the methods of attacking those problems, and of the results to be expected from intelligent community action in the public health field.

Cornell, at its founding in 1868, required a 30-lecture course in hygiene for every student in his first year. This requirement continued until 1904, when it was abolished and a course in hygiene was offered but not required. This scheme continued until the fall of 1919, when hygiene again became a required subject, this time a 60-lecture course. These lectures are given by the physicians of the medical adviser's office to the freshmen and sophomore class divided into groups averaging 135 members each and meeting once a week. The lectures are 50 minutes in length and are supplemented by considerable demonstration material and by charts. A notebook and a

[12] Report of meeting of American Public Health Association, Atlantic City, May 18, 1926, New York Times, May 19, 1926

preliminary examination are required each of the four terms. The final examination is waived where the term's average in notebook, preliminary examination, and attendance is 85 per cent or better. The "hygiene requirement" is administered by the dean of the university faculty and the Faculty Committee on Instruction in Hygiene and Preventive Medicine No credit is given, but the satisfactory completion of four terms' work in hygiene is a university requirement for graduation. Following is the schedule of lecture topics of the past year (1925-26):[13]

OUTLINE OF LECTURE SCHEDULE

HYGIENE I—PERSONAL HYGIENE

1 The health program at Cornell University—Factors that influence health
2 Bacteria and disease—The development of the germ theory
3. Infection and resistance.
4 Immunity.
5. The hygiene of the nose and throat—Nasal obstruction; tonsils and adenoids; ear trouble
7. "Colds"—Are they preventable?
8 The personal prevention of tuberculosis
9 The preventable causes of mental disease
10. The causes and prevention of nervousness.
11. The importance of positive health to the individual and to the community
12. The structure and physiology of the genital system
13. The mechanism of reproduction—The development of the sex instinct—Hygiene of sex.
14. The venereal diseases.

HYGIENE II—PERSONAL HYGIENE

1. Foods—Types and amounts needed
2 The mechanism of digestion, absorption, storage, and utilization—The prevention of indigestion and constipation.
3 The hygiene of vision.
4. The functions and care of the skin.
5. The hygiene of growth
6. Teeth and their care
7. Posture and health
8. The hygiene of the circulatory system and kidneys
9. The muscles and exercise—The benefits of exercise.
10. Safeguarding athletics—Exercise facilities at Cornell.
11. Heredity and health.
12. The emergency treatment of unconsciousness—Artificial respiration.
13. The emergency treatment of wounds
14. Why an annual physical examination?—Results of examination of freshman class.

HYGIENE III—HYGIENE OF ENVIRONMENT

1. Man the most frequent source of infection for man—Epidemiology—Carriers.
2. Animals as sources of infection for man.
3. Air and disease—Climate and disease
4. Ventilation.

[13] The sex-hygiene content of these lectures has been published in Health Education Program, Cornell University, by D F Smiley Social Pathology, Vol. 1, No 5. United States Public Health Service

5 Soil and disease
6. Water and disease.
7 The provision of a safe water supply
8 Sanitary housing—Sanitary disposal of wastes
9 Food deficiencies, poisons, infections, adulterations
10 Milk and meat—Their proper production and handling
11 Alcohol, tobacco, coffee, and the narcotic drugs.
12 Nostrums and quackery
13 Insects and disease
14. Occupational health hazards

HYGIENE IV—PUBLIC HEALTH

1 The development of public health and preventive medicine
2 Community problems in mental hygiene—Mental disease. mental deficiency, delinquency, drug addiction
3 Community problems in sex hygiene—Venereal disease, illegitimacy, prostitution, divorce.
4 Tuberculosis and the community.
5 The problem of the diseases of middle life—The degenerative diseases and cancer.
6 The community's interest in maternity and infancy.
7 Safeguarding the health of school children
8 The health of the industrial workers
9 Military hygiene
10 The place of the voluntary health organizations in public health work.
11 Official health agencies
12 Physicians versus quacks—The problem of providing good medical care.
13 Nurses and hospitals—The problem of providing good hospital and nursing service
14. The cost versus the results of public health work.

Research.—Some of the most striking opportunities for research, peculiar to the field of health education in colleges and universities, are, we believe, along the following lines, though the numerous possibilities make choice difficult: Statistical study of morbidity rates for such minor disorders as "colds" and "grippe"; study of the effects of exercise upon the heart, kidneys, and blood vessels; study of albuminuria and glycosuria to determine type and cause; statistical study of afterlife of persons showing minor abnormalities such as slight hypertension or albuminuria or glycosuria or recurrent jaundice while in college; statistical study by questionnaire method to determine what constitutes the normal condition in regard to frequency of bowel movement, frequency of headaches, frequency of vomiting attacks, and any possible relationship to health habits; study of the results of vaccine therapy in cases of recurrent "colds," acne, furunculosis; study of the results of desensitizing treatment for hay fever; statistical study of the results of health educational work in the university.

Along all these lines we have been working and have attained some rather encouraging results. We hope that time will bring forth results in greater measure; but even in the absence of remarkable

findings the stimulation which accompanies research is a factor to be reckoned with throughout all the work of the department A university department of health which does not provide time and incentive and some facilities for research can not hope, we believe, to maintain a high standard either of work or of workers

VI MEASURING THE RESULTS OF THE HEALTH EDUCATIONAL PROGRAM

Most of the results of a health educational program are not measurable, most of the results are to be seen in the future rather than in the present Yet measurable results of our work are continuously being sought, and, after a fashion, we can begin to estimate roughly our successes and failures

In 1919–20 Dr Haven Emerson [14] found that, at Cornell University, 1.6 per cent of the school days available to the student body during the year were lost as the result of illness, 2 4 per cent being lost by the women, and 1.5 per cent being lost by the men During the past year (1925–26), and in spite of a heavy March influenza epidemic, the undergraduate student body lost only 1.28 per cent of the school days available, the women 1.8 per cent, the men 1.1 per cent. We believe that Cornell students are losing less school time as the result of illness than they did five years ago.

Another method of measuring our results is to be tried during the coming year, 1926–27. Using the table of defects and faulty health habits appended, we will mark each student at the time of the annual physical examination, deducting 5 per cent for every faulty health habit and every remediable defect found and marking on the basis of 100 per cent. We will thus rate each individual upon his health upkeep, and not penalize him for his health inheritance, or irremediable health deficit. An average health upkeep rating of about 85 per cent is what we think we have in our present entering class; an average health upkeep rating of 100 per cent is what we can aim to get in that same class at graduation. Certain it is that if health knowledge *can* prevent disease and foster health it ought to do ~~so to~~ a measurable degree in a period of four years among a group of college students

HEALTH UPKEEP GRADING TABLE [15]

Each group is valued at 5 per cent. Even 1 defect in a group subtracts the 5 per cent of the whole group.

1 *Nutrition*

More than 10 per cent underweight
More than 10 per cent overweight

2. *Posture*.

C or D grade of postural abnormality—
Stoop neck.
Round hollow back.
Drop shoulder.

---

[14] Education in Health at Cornell University By Haven Emerson et al American Journal of Public Health, April, 1921

[15] [illegible]cations have been made in this table to adapt it to use for the women students.

3. *Vaccination*
   No vaccination mark and no history of smallpox
4. *Eyes*
   Vision 20/24 or less and not properly corrected by glasses.
   Vision 20/13 or more and not properly corrected by glasses.
5. *Ears*
   Discharging ear, not under treatment
   Impacted cerumen plugging entire canal
   Deafness, uninvestigated by specialist.
6. *Nose*
   Defects causing symptoms, yet uninvestigated by specialist.
7. *Sinuses*
   Chronic sinus infection, not under treatment
8. *Teeth*
   Uncorrected dental caries
   Abscessed teeth
   Marked tartar deposit
   Dead tooth not examined by X ray within two years
   Pyorrhea, not under treatment
9. *Tonsils.*
   Tonsils judged chronically infected from history and appearance.
10. *Hernia*
11. *Veins.*
   Hemorrhoids or varicose veins (operable).
12. *Genitals*
   Phimosis
   Large varicocele threatening atrophy of testes or causing pain.
   Hydrocele.
13. *Feet:*
   Improper posture of feet, grade C or D.
14. *Stimulants*
   Using more than—10 cigarettes a day, or
   5 pipefuls a day, or
   2 cigars a day, or
   2 cups of coffee a day, or
   2 cups of tea a day
15. *Bathing*
   Bathing less than twice a week.
16. *Eating habits*
   Indigestion and hurried meals
   Indigestion and eating irregularly.
   Indigestion and improper diet.
17. *Evacuation habits*
   Bowels constipated, and not given chance to move at regular time at least once a day.
18. *Exercise habits*
   Exercising less than—
   One hour a day walking.
   Two hours a week vigorous exercise.
19. *Sleep habits:*
   Less than 8 hours sleep, with fatigue symptoms.
20. *Recreational habits:*
   One hour a day through the week.
   One-half day on Saturday or Sunday, in addition to exercise time.

Some Federal Safeguards of the Manufacture and Distribution of Diphtheria Toxin-Antitoxin Mixture

Diphtheria toxin-antitoxin mixture has in the last few years come into such general use in the prevention of diphtheria as to occupy a place of importance in the preventive immunization against disease probably second only to smallpox vaccine. Every year thousands of children are immunized, and the effect of this excellent prophylactic measure is being reflected in the lowered diphtheria rate which is evident in localities where much work has been done along this line. This result in the control of a dreaded disease of early childhood is all the more gratifying in that immunization is accomplished with practically no local or general reactions in the inoculated children. Very young children unquestionably take toxin-antitoxin mixture better even than those of school age, the ideal age for producing immunity being around the end of the first year of life. By this time the child will have lost the immunity acquired from the mother and will soon begin to come more generally into contact with other children, with the increase in danger of acquiring diphtheria. Heaviest mortality rates from diphtheria are encountered in children below the school age, and it is probably safe to say that the immunization of one child of this group will equal the immunization of five school children in effect on the diphtheria death rate. Some means of reaching this very important group of children is very much needed.

Toxin-antitoxin mixture is prepared only in establishments holding license issued by the Secretary of the Treasury, upon recommendation of the Public Health Service The service, through the hygienic laboratory, insures that the establishment is properly equipped with both physical apparatus and properly trained personnel to carry out the careful technique of manufacture and testing before recommending a license. This information is obtained always by means of a careful personal inspection by an officer of the Public Health Service.

The product is prepared, as the name indicates, from diphtheria toxin and diphtheria antitoxin, mixed in such proportions that the former, a poison derived from the diphtheria bacillus, is almost, but not quite, neutralized by the antitoxin, which is obtained from the blood of a highly immunized horse Very careful, accurate testing is always done on each lot.

The toxin is usually prepared in the establishment and allowed to age for at least one year By this time the first rapid deterioration will have taken place. The strength is next accurately determined by inoculation in guinea pigs weighing 250 grams (8–9 ounces). One drop of a good toxin is sufficient to prepare three doses, or one course of immunizing treatments of toxin-antitoxin mixture.

The antitoxin is a specially selected, highly concentrated product, as it is derived from the serum of the horse and it is desired to keep the dose as low as possible. One drop of a good antitoxin is sufficient to prepare 2,000 doses of toxin-antitoxin mixture The antitoxin is also aged to make stable, and then very carefully tested to determine the exact strength expressed in units per cubic centimeter. Guinea pigs are also used for this test

These two products are next diluted with sterile phenolized salt solution and mixed in such proportions that five human doses will kill a 250-gram guinea pig in from 6 to 20 days, while one human dose will cause a local reaction in the guinea pig, but will only cause paralysis in from 15 to 30 days. It is thus seen that the amount which shows no acute symptoms in the very susceptible guinea pig weighing one-half pound, could not possibly harm a child weighing from 20 to 80 pounds. This exact degree of toxicity is difficult to obtain, and can only be secured by careful measurements of ingredients, the strengths of which are accurately known. Frequent adjustments and re-tests are usually required.

After the mixture is completed and adjustments of toxicity are made the entire lot is filtered to sterilize, and final toxicity and sterility tests are applied by the manufacturer. If these tests are satisfactory and the manufacturer considers the mixture suitable for the market, samples of each lot are sent to the Hygienic Laboratory, where sterility and guinea-pig tests are also made. No lot is released for distribution until tests at the Hygienic Laboratory are satisfactorily completed.

Owing to the tendency of diphtheria toxin to deteriorate, and particularly when diluted, this product is allowed to remain on the market for only six months, and precautions should be taken to keep in a cold place but not allow it to freeze. Freezing causes a slight turbidity to appear and renders the product inactive.

With the present type of mixture which is in universal use, the original toxin content is one-thirtieth that of the older mixtures, the product is water clear, and with the great care in manufacture, with check testing by different laboratories, the public is assured a safe and effective product which may be employed with confidence.

SPECIAL COURSES FOR PHYSICIANS IN TREATMENT OF VENEREAL DISEASE

Surgeon General Hugh S. Cumming has announced that the United States Public Health Service, as a part of its cooperative work with State health departments in the control of venereal diseases, will give special courses of training to physicians, clinicians, and health officers at its venereal disease clinic, Hot Springs, Ark.

This clinic, which is operated by the Public Health Service in a new building belonging to the Department of the Interior, offers exceptional opportunities for the study of the venereal diseases, especially in clinical and laboratory diagnosis, treatment methods, and clinic management. Here studies of the many practical and scientific problems connected with venereal-disease control are carried on. Last year 3,570 indigent persons were examined at the clinic, and 3,064 cases of syphilis and gonorrhea were diagnosed and given a total of 32,315 treatments.

Surgeon General Cumming states that the instruction courses which now are offered will consist of a series of lectures by the director and the consulting specialists attached to the clinic, demonstrations in laboratory and treatment methods, and practical experience in the diagnosis and treatment of syphilis and gonorrhea in various stages through participation in the routine work of the clinic. New classes of not more than 10 physicians will form on the 1st of each month and the course will continue for a minimum of 30 days. Engraved certificates will be presented by the Public Health Service to those who satisfactorily complete the 30-day course.

Fees are not charged for this course of instruction. The individual physician, however, will necessarily provide his own travel expense to and from Hot Springs and his living expenses while there.

Interested physicians should write to the local State health officer or to the Surgeon General, United States Public Health Service, Washington, D. C., for information or application blanks Applications should be indorsed by the State health department in which the applicant resides before being submitted to the United States Public Health Service.

THE "DEADLINESS" OF A DISEASE

The following is quoted from the Vital Statistics Bulletin of the Pennsylvania Department of Health for October, 1926:

"When you say a disease is 'deadly,' just what do you mean? Thus, during the first seven months of this year, measles killed six times as many people as did typhoid fever On the other hand, measles killed only one out of every hundred people it attacked, whereas typhoid killed one out of every five patients Which, then, is the more 'deadly' disease? If you are a physician, typhoid is of course the more deadly; that is, it offers the most unfavorable prognosis. If you are a health official, measles is the most deadly, in that it kills off more people in your jurisdiction.

"Vital statistics should answer both sides of the question, and we present herewith, as a supplement to the 'Mortality Rates' routinely published, 'Case Fatality Rates' for the first seven months of 1926 for the State as a whole. These represent the number of deaths reported for each hundred cases of the particular disease.

Diphtheria	10 5
Measles	1. 1
Scarlet fever	1 3
Typhoid	18 5
Whooping cough	5 8

"These rates are all, of course, a little too high, due to the present incompleteness of case reporting. They are, however, of value in that they show the relative seriousness of these diseases from the patient's or attending physician's viewpoint.

"OUTSTANDING RESULTS

"The chart presented with this issue impressively tells the story of the subjection in Pennsylvania of two dread diseases, tuberculosis and typhoid It is seen that during the period the State department of health has been in existence the death rate from tuberculosis has been reduced 48 per cent while that from typhoid has been reduced 91 per cent. What better argument can be presented for the effectiveness of pure water, pure milk, better sanitation, and better health habits?"

The chart shows that tuberculosis deaths were reduced approximately from 150 to 77 per 100,000 and typhoid fever from 56 to 4.8 per 100,000 during the period 1906 to 1925.

PUBLIC HEALTH ENGINEERING ABSTRACTS

City Authorities Held Responsible for Typhoid. Anon *Canadian Engineer*, vol 50, No. 26, June 29, 1926, pp. 697–698 and 716 (Abstract by Rudolph E. Thompson)

The full text is given of Justice Logie's judgment in case in which the city of Owen Sound, Ontario, the public utilities commission, and the local board of health were sued for damages by a girl who contracted typhoid during an epidemic in September, 1925. The plaintiff was awarded damages of $2,000 with costs Justice Logie stated that the evidence presented was fully convincing that the typhoid was water-borne, and he severely rebuked the civic authorities for gross negligence in disregarding repeated warnings that the water supply was of dangerous quality. Despite instructions from the provincial board of health that steps be taken to insure the safety of the supply and reports from the local representative of the provincial board that the quality of the water was unsatisfactory, chlorination was postponed until it was too late. It was brought out in evidence, brief extracts from which are included, that some time previous to the epidemic an old reservoir was put into service which had been closed on the recommendation of the provincial board of health in 1916, when there was typhoid among the troops quartered in Owen Sound. When this connection between the reservoir and the city supply was closed, the epidemic abated.

Survey shows Relation of Goiter to Drinking Water. Anon. *The Nation's Health,* vol. 8, No 8, August, 1926, pp 557–559. (Abstract by H. N. Old.)

The city of Saginaw, Mich , is taken for this survey of goiter prevalence in school children and the relationship of drinking water In this city examinations of the deep-well water supplies used indicated an average iodine content of 0.31 milligram per gallon, varying from 0 024 to 1.4, while absent in shallow wells

Tables are given showing the analyses of the deep-well waters, and also tables showing the prevalence by schools, and by grades at one school, of thyroid enlargement among the children

The conclusion is reached that this enlargement does not occur among children who use deep-well water regularly, and the evidence seems to indicate quite clearly that (1) there is a definite relation between the incidence of goiter and the kind of drinking water used; (2) those who have used water from deep wells regularly have benefited by its use in both the prevention and decrease of thyroid enlargement; (3) we are led to believe that even the minutest quantity of iodine in drinking water (0.024 milligram per gallon) if regularly used is sufficient to prevent thyroid enlargement

Chlorination in Relation to Factors of Safety for Water Filtration Processes. H. W. Streeter, Sanitary Engineer, United States Public Health Service. *Water Works,* vol 65, No. 9, September, 1926, pp. 439–442. (Abstract by E. A. Reinke.)

This paper is a memorandum based on a survey of 17 water filtration plants on the Ohio River submitted as an appendix to the committee report presented at the conference of State sanitary engineers at Buffalo, N. Y., June, 1926. Tables and charts show the relation between *B. coli* index and frequency with which on individual days it exceeded specified limits; the relation between *B coli* index of raw water and unchlorinated effluent; and assumed factors of safety attributed to chlorination necessary to give a specified chlorinated effluent for certain *B. coli* indices in unchlorinated effluent.

Mr. Streeter suggests as a basis for compromise between those who would demand an unchlorinated effluent conforming to the Treasury Department standard and those who are satisfied with chlorinated effluents meeting the standard, "that instead of taking chlorination as the factor of safety, a definite numerical factor be assigned such that the average *B. coli* index of the chlorinated effluent shall be some specified fraction of the maximum limit prescribed by a given standard of quality, as, for example, the revised Treasury Department standard. Thus, if the factor of safety be five, the required average *B. coli* index of the chlorinated filtered effluent would be not greater than 0.2 per 100 cubic centimeters." After discussing several possible conditions,

Mr. Streeter suggests as a basis for working factors of safety the following table:

Class	Factor of safety	Limiting yearly average B coli index per 100 c c	
		Chlorinated filter effluent	Unchlorinated filter effluent
A	10	0 10	3 2
B	5	20	4 6
C	3	33	5 7

Raw waters would be put in class A, B, or C, depending on the difficulty experienced in treating them

Water Purification in Relation to Stream Pollution.—*Waterworks,* volume 65, No. 9, September, 1926, pp. 447–449. (Abstract by E A. Reinke.)

The paper is the progress report of committee on water supply and purification presented at the conference of State sanitary engineers, Buffalo, N Y., June, 1926.

A survey of 17 municipal water filtration plants "has indicated that the average fully equipped plant of modern design operated efficiently under skilled supervision and treating a water similar in its general character to that of the Ohio River, should be able to produce a chlorinated filter effluent showing an average conformance to the revised Treasury Department *B. Coli* standard when the mean *B. coli* index of the raw water does not exceed approximately 5,000 per 100 cubic centimeters." Modern tendencies may be to rely too much on chlorination, using filtration merely for clarifying water. Efficiency of bacterial removal is not greatly effected by raw water turbidity or changes in season. Most probable numbers of *B. coli* is most satisfactory measurement of bacterial relationships. A more precise and more highly standardized method of enumerating B. coli should be adopted. A definite specification should be made as to the maximum permissible bacterial or *B. coli* content of unchlorinated or chlorinated water, and this will depend upon extent to which chlorination is considered a "factor of safety."

Zoning on Trial Before the United States Supreme Court.—James Metzenbaum. *American City,* volume 35, No. 1, July, 1926, pp. 74–76. (Abstract by George N. McDaniel, jr.)

A zoning ordinance passed by the village of Euclid, Ohio, has been assailed by the Ambler Realty Co. charging that such an ordinance is unconstitutional. The question as to the reasonableness of the Euclid ordinance is, in itself, of negligible importance, but a ruling concurring with the realty company would affect zoning ordinances

all over the country. Several State supreme courts have passed on the validity of zoning ordinances, and at the present their opinions are equally divided The Euclid case will be reargued before the United States Supreme Court this fall.

An Investigation Concerning the Incidence of Lead Poisoning in Motor-Car Painters.—C. Badham (Studies in Industrial Hygiene, No. 6), Report Director General of Public Health, New South Wales for 1924, 90–100 (19 refs.) (Abstracted by E. L. Collis) From *Bulletin of Hygiene*, volume 1, No. 8, August, 1926, page 643 (Abstract by Arthur P Miller.)

"An investigation, during which 100 men exposed to risk of lead poisoning in the motor-car painting trade were examined, is made the text for an unusually interesting discussion of our present knowledge with regard to plumbism. The incidence of lead poisoning was found to be grave; 14 men were classed as clear cases of lead poisoning, 12 as slight cases, and 17 as suspicious, while 11 had other nonoccupational disabilities. The prohibition of lead compounds in the paints used is indicated. A blue line on the gums is not confined to lead exposure, as it has been found in 25 per cent of men receiving injections of bismuth at a venereal-disease clinic, but when due to lead it is a danger signal. Like lead in the urine, it indicates active transportation of lead in the system. The term 'lead absorption' is objected to as a mere euphemism for minor poisoning. Punctate basophilia was found in 18 of the motor-car painters, but was entirely absent among 25 painters using nonlead paints on bedsteads and among men receiving bismuth injections. Thirteen of the 100 had granular casts in their urine, an unusually high proportion, but the group as a whole showed no evidence of blood pressure being unusually high or low. Detailed information is given in tabular form of each examination made."

Relation of Health Departments to Industrial Hygiene.—C. T. Graham-Rogers, M. D. *American Journal of Public Health*, volume 16, No. 2, February, 1926, pages 117–120. (Abstract by A. L. Dopmeyer.)

The first accomplishment desired in industrial hygiene work is coordination with the work of the various agencies in the State and cooperation between State and local authorities. Factors within and without the industry responsible for accidents and health hazards, and remedial measures, are discussed.

Methods for satisfactory cooperation between various agencies are suggested, and a plea is made for better observance of the laws and simplification of inspection work by elimination of duplication.

DEATHS DURING WEEK ENDED OCTOBER 30, 1926

Summary of information received by telegraph from industrial insurance companies for week ended October 30, 1926, and corresponding week of 1925. (From the Weekly Health Index, November 3, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Oct. 30, 1926	Corresponding week, 1925
Policies in force	65,729,006	61,864,119
Number of death claims	11,573	10,672
Death claims per 1,000 policies in force, annual rate	9.2	9.0

Deaths from all causes in certain large cities of the United States during the week ended October 30, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925. (From the Weekly Health Index, November 3, 1926, issued by the Bureau of the Census, Department of Commerce)

Vermont	0	9	0		386		1	12	0	6

[1] Including paratyphoid fever.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended October 30, 1926, 37 States reported 2,290 cases of diphtheria. For the week ended October 31, 1925, the same States reported 1,904 cases of this disease. Ninety-nine cities, situated in all parts of the country and having an aggregate population of more than 29,800,000, reported 1,221 cases of diphtheria for the week ended October 30, 1926. Last year for the corresponding week they reported 984 cases The estimated expectancy for these cities was 1,256 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-six States reported 2,119 cases of measles for the week ended October 30, 1926, and 1,312 cases of this disease for the week ended October 31, 1925. Ninety-nine cities reported 352 cases of measles for the week this year, and 583 cases last year.

Poliomyelitis.—The health officers of 37 States reported 60 cases of poliomyelitis for the week ended October 30, 1926. The same States reported 113 cases for the week ended October 31, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 2,543 cases; last year, 2,163 cases; 99 cities—this year, 966 cases; last year, 869 cases; estimated expectancy, 757 cases.

Smallpox—For the week ended October 30, 1926, 37 States reported 197 cases of smallpox. Last year for the corresponding week they reported 208 cases. Ninety-nine cities reported smallpox for the week as follows: 1926, 17 cases; 1925, 56 cases, estimated expectancy, 36 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Seven hundred and seventy-seven cases of typhoid fever were reported for the week ended October 30, 1926, by 37 States. For the corresponding week of 1925, the same States reported 831 cases of this disease. Ninety-nine cities reported 159 cases of typhoid fever for the week this year and 140 cases for the corresponding week last year. The estimated expectancy for these cities was 136 cases

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 93 cities, with a population of more than 29,150,000, as follows: 1926, 598 deaths; 1925, 691 deaths

City reports for week ended October 30, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended October 30, 1926, compared with those for a like period ended October 31, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925, and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, September 26 to October 30, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C. PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain· (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

VOL. 41 NOVEMBER 26, 1926 NO. 48

DISTRIBUTION OF ENDEMIC GOITER IN THE UNITED STATES AS SHOWN BY THYROID SURVEYS

By ROBERT OLESEN, Surgeon, United States Public Health Service

A knowledge of the distribution of endemic goiter in the United States is essential both to an understanding of the causation of the malady and the intelligent application of prophylactic measures. Obviously, when accurately determined fluctuations in distribution are known, clues to the remote etiology of simple thyroid enlargement will be nearer at hand Likewise, a knowledge of distribution enables the formulation of effective plans for prophylactic endeavor. In the present article an effort has been made to assemble the known facts concerning the distribution of endemic goiter in the United States. While due diligence has been exercised in compiling the data, it is probably far from complete However, the publication of a list of thyroid surveys may cause additional work of similar character to be made known.

Goiter among drafted men.—Prior to the World War no information concerning the nation-wide distribution of goiter was available, for relatively few surveys had been made. The draft examinations, however, provided valuable information concerning both simple and exophthalmic goiter. Manifestly, the draft examinations, particularly as they applied to goiter, were subject to certain unavoidable handicaps which, to some extent, affected the accuracy of the observations. In the first place the subjects of the examinations were men of military age, in whom endemic goiter is likely to be less prevalent than among adolescent girls Secondly, the examiners were physicians with varying degrees of skill and experience in diagnosing thyroid disorders. Consequently the various findings may not be strictly comparable with each other.

Another difficulty with the draft figures, as customarily presented, is the failure to indicate variations in distribution of goiter within the individual States. Inasmuch as differences in goiter incidence within relatively small areas are common, it is desirable that the information derived from the draft examinations be supplemented. However, even with their manifest limitations the draft figures represent a reliable general index of nation-wide goiter incidence.

Table 1, in which is shown the incidence of endemic goiter among men examined for military service during the World War, is reproduced because of its continued interest. Generally speaking this tabluation indicates a greater frequency of the malady in the Pacific Northwest and in the Great Lakes Basin.

TABLE 1 —*Number of instances of endemic goiter and ratio per 1,000 examinations among 2,510,701 men examined for military service in the United States during the World War (by States)* [1]

State	Number of cases	Ratio per 1,000	State	Number of cases	Ratio per 1,000

[1] Table 18, p 111, of Defects Found in Drafted Men, by A G Love and C B Davenport Prepared under the direction of the Surgeon General, M H Ireland, War Department, Washington, D. C., 1920

Independent thyroid surveys —In addition to assembling again the findings of the draft examinations there are presented in the present article the results of thyroid surveys made in various sections of the United States. Quite naturally the results of independently made goiter surveys can be accepted only after making due allowances for the conditions under which the figures were secured This reluctance to accept the findings is due to several causes.

The chief difficulty in comparing goiter statistics in different sections of the country arises from the fact that the dividing line between the normal and enlarged thyroid gland is not definitely known. Consequently a thyroid which is considered normal in a section having a considerable incidence may be regarded and often is recorded as a definite enlargement in districts of slight prevalence.

Another obvious defect in thyroid surveys made by independent workers results from the failure to employ similar methods of examination, as well as a common means of classifying the several degrees of goiter detected. These facts, when considered in connection with the varying skill and experience of the examiners,

militate to a considerable extent against the usefulness of the data for purposes of comparison.

However, the information derived from the various surveys is of value as illustrating the widespread interest which is being taken in the solution of the goiter problem Moreover, the evidence adduced by thyroid surveys among individuals of elementary grades, high school, and college, is largely confirmatory of the results of the draft figures

An interesting point which has been brought out in connection with the goiter surveys is the finding of goiter in places in which its presence has heretofore been unsuspected Many variations in incidence would undoubtedly be brought to light by additional systematic surveys Consequently, valuable data relating to goiter would become available.

How the data were secured—The material presented in Table 2 was obtained from two principal sources. First, by consulting the literature and, second, by direct correspondence with all State, county, and city health officers in the United States, the last-named officials being located in communities with populations in excess of 10,000 More than 95 per cent of the health officers from whom information was requested by the Public Health Service, promptly submitted replies concerning the presence or absence of simple thyroid enlargement. In many instances valuable collateral comment was forthcoming at the same time

In Table 2 the available information has been arranged to show the number of persons of each sex examined and also the percentage of thyroid enlargements recorded In some instances this information is not complete, in others, only estimates are presented. From the many localities not listed in Table 2 the information was elicited that thyroid surveys had not been made. However, sufficient survey data are at hand to enable the formulation of rather definite opinions concerning the distribution of simple goiter in many sections of the United States.

In several places, among which may be mentioned Rochester, N. Y , Lorain, Ohio, and Aroostook County, Me , resurveys have been made. Provided such reexaminations are conducted by the same observers, under similar conditions, the resulting information serves to indicate changes, or lack of changes, which have either occurred naturally or followed the institution of prophylactic measures. Authentic facts of this character are valuable contributions to the epidemiology of goiter.

The need for uniformity in making surveys—Particularly noteworthy in the tabulation of surveys is the irregularity of goiter distribution within many States. This condition may be due either to actual variations in incidence or to differences in the methods of

examination employed by the examiners. Conceding the desirability of a more accurate knowledge concerning the distribution of endemic goiter in the United States, there would appear to be need for careful schooling of examiners in diagnostic procedure, thereby insuring findings of comparable character Particularly valuable in obtaining such results are personal study and practice, supplemented by instruction from persons familiar with normal and abnormal thyroid glands

Instructions for making thyroid surveys are available in several publications.[2] However, for practical purposes a theoretical knowledge can not supplant the advantages accruing from actual experience. As procedure becomes standardized it is conceivable that valuable information regarding the epidemiology of goiter will be forthcoming Furthermore, such data will be useful in encouraging the application of prophylactic measures where they are most needed.

In this connection it should be pointed out that a thyroid survey is a time-consuming procedure and is not to be undertaken to the exclusion and detriment of more important public-health projects. Frequently a thyroid survey can be made as a collateral portion of general physical examinations. When this policy is pursued, time is conserved, and at the same time possible correlations between thyroid enlargement and other physical states may be indicated.

SUMMARY

1. The distribution of goiter in the United States, as disclosed by numerous thyroid surveys, parallels the goiter findings among drafted men.

2. There are manifestly wide variations in the methods of determining thyroid enlargements. The classifications of various degrees and types of involvement also range within wide limits. Uniform procedure is a necessity if findings in different sections of the country are to be compared.

3. Based upon incidence, wholesale prophylaxis for endemic goiter is apparently not required in all States.

4. Individual thyroid surveys disclose foci of endemic goiter in localities not previously regarded as being located in goitrous territory.

5. Resurveys are desirable for the purpose of learning the extent and character of changes occurring either under natural conditions or after widespread prophylaxis has been instituted.

REPORT OF THE COMMITTEE ON SANITARY CONTROL IN THE DEVELOPMENT OF GROUND-WATER SUPPLIES [1]

This report considers the sanitary defects affecting the safety of water obtained from various types of ground-water supplies and the safeguards which should be employed to remedy same Examples are given of towns in which epidemics have occurred due to the various defects It is of interest to note that a survey of engineering literature and correspondence incident to the preparation of this report revealed 40 authentic epidemics of typhoid, dysentery, or intestinal disorders, attributed to infection of ground-water supplies. This number is, of course, only a portion of all those which have occurred from this cause, but it serves to impress us with the urgent need of properly safeguarding our new and existing ground-water supplies against these known dangerous sanitary defects

The first epidemic of which we find record was that occurring at Mankato, Minn., in 1908, with 5,000 cases of diarrhea, 511 cases of typhoid, and 35 deaths. A decision of the Minnesota Supreme Court, arising from a suit brought on account of this epidemic, holds that a municipality is liable for sickness and deaths resulting from the pollution of the public water supply. Probably the largest epidemic was that occurring at Salem, Ohio, in 1920, resulting in 884 cases of typhoid and 27 deaths in a population of 10,000. The most recent large epidemic was that occurring in Santa Ana, Calif , in 1923, resulting in 308 cases of typhoid.

A code of principles summarizing the safeguards necessary to prevent pollution of ground-water supplies is attached to this report. References to articles describing the epidemics and others giving detailed discussions of the various sanitary hazards and safeguards are given in Appendixes A and B The detailed report outlining the various sanitary defects occurring on ground-water supplies and corresponding safeguards follows. For the purpose of this report, ground-water supplies are separated into the following four groups: Wells, springs, mine water, and infiltration galleries.

GENERAL

Defects common to all types of ground-water supplies include the following:

(1) Poor location of the source of a ground-water supply as to surface drainage, flooding in times of high water, and proximity to sources of surface or sewage contamination, such as streams,

---

sewers, abandoned uncapped wells, sink holes, privy vaults, and pits, cesspools, sewage wells, and other leaching devices for sewage.

EPIDEMICS: Bad Axe, Mich.; Corning N. Y.; Watervliet, N. Y.; Walden, N. Y.; Bethlehem Mines, W. Va.; Tuscola, Ill.

SAFEGUARDS: These conditions should be remedied, according to the particular circumstances, by establishing a supply in a new location, by furnishing adequate surface protection and eliminating sources of sewage pollution, or by adequate treatment. Chlorination alone may be sufficient when the contamination is slight. All wells should be tightly capped before abandonment to prevent accidental contamination of a water-bearing stratum. Sewage wells are a menace and permissible only under exceptional circumstances. Shallow wells, springs, and infiltration galleries used as a source of municipal supply should preferably be located outside the built-up area of a town to remove them from sources of contamination. The sewer from a toilet in a pumping station should be constructed of cast-iron pipe for a distance of at least 50 feet from the source of supply, suction or gravity piping, or reservoir.

(2) Suction or gravity piping located so that a leak developing in same will permit contamination of the supply. Proximity to sewers or other sources of pollution is particularly dangerous.

EPIDEMICS: Salem, Ohio; Benson, Minn.; Martinsburg, W. Va.; South Pasadena, Calif.; Greenville, Ill.; pollution at St. Louis, Mich.

SAFEGUARDS: All suction piping in a pump room should be run exposed, well above the floor level. All gravity and suction lines located in the ground should be constructed with water-tight material and joints, preferably cast iron, and never with sewer pipe. These lines should be located at a safe distance from sources of pollution and tested frequently with pressure to determine tightness. All sources of pollution which would contaminate supply if lines leaked should be carefully determined. If sources of sewage pollution are within a dangerous distance or if the line leaks, the condition should be remedied as circumstances warrant, such as by removing source of pollution, changing location of pipe, repairing leaks, or providing purification. Gravity and suction lines passing through polluted streams should be avoided or continuous purification provided.

(3) Collecting or storage reservoir and receiving or suction well subject to contamination on account of improper location or construction.

EPIDEMICS: New Ulm, Minn., Brenham, Tex.

SAFEGUARDS: The reservoir location should be at a safe distance from sources of sewage pollution and safe from flooding. The reservoir should be of continuous concrete construction with water-tight bottom, sides, and top, using 4 to 8 pounds of hydrated lime per

sack of cement or an approved waterproofing preparation. Brick construction is unsatisfactory. All openings should be satisfactorily protected from dust, small animals, and willful pollution; providing manhole openings with raised edges and overlapping locked covers and pipe ventilators with openings screened and pointing down. Clean-out, drain, or overflow pipes should under no conditions be connected direct to a sewer or installed in a manner such that they will be subject to a back flow of surface water or sewage during high-water periods.

(4) Connection of a safe source of ground-water supply with a polluted water supply. Many times old forgotten piping permits pollution of the source of a safe supply. The connection of the source to a body of polluted water, protected from it only by the maintenance of a higher level, or other arrangement, is often the cause of contamination through careless operation.

EPIDEMICS. Schenectady, N Y ; Cochrane, Ontario

SAFEGUARD: Complete elimination of these connections.

WELLS

(5) The sanitary defects permitting the pollution of well supplies at the surface include the following:

(*a*) Connection of well pit or subground level pump room to a sewer or drain subject to back flow.

(*b*) Lack of adequate facilities for removing seepage or waste water from a well pit or pump room.

(*c*) Lack of a water-tight connection on cased wells to close the annular opening between the well casing and pump column (sometimes called drop pipe or suction pipe).

(*d*) Lack of a water-tight top for dug and bored wells.

(*e*) Failure to locate properly and protect the air inlet on air-lift pumping systems.

EPIDEMICS: Mankato, Minn.; Santa Ana, Calif.; Lansing, Mich.; Benson, Minn.; pollution at Montgomery, Ala.

SAFEGUARDS: (*a*) A well pit or subground level pump room should be avoided whenever practicable and the pumps installed on a pump-room floor located above the surrounding ground level.

(*b*) If conditions necessitate the installation of a well pit or subground-level pump room, the floor and walls should be made water-tight and drained to an open outlet (under no condition connected to a sewer), or a sump and automatic ejector should be provided to remove the waste water.

(*c*) The outside casing or curbing of wells should be extended above the level of the ground or floor of the pump room or pit, and a water-tight connection installed to close the annular opening between the well casing and pump column or drop pipe. Dug wells

should be provided with a water-tight cover, and the pump pipe, manhole, and other openings should be properly protected so as to prevent waste water or other contaminating material from entering the well. Pumping equipment should not be installed in the well in a manner requiring entrance of an attendant.

(*d*) On air-lift pumping system the air inlet should be properly located and protected to minimize the entrance of dust and other contaminating material.

A set of suggested regulations has been formulated covering the installation of well-pumping machinery for the benefit of consulting engineers, well and pump contractors, and manufacturers of pumping machinery, and is given in Appendix C.

(6) Sanitary defects permitting underground contamination of well supplies are as follows

(*a*) Failure to extend a water-tight outside well casing or curbing to a sufficient depth and to seal the bottom into a solid formation, permitting contaminated surface and shallow ground water or other pollution to drain into the well. This is found dangerous, particularly in strata consisting of limestone lava flows, and similar strata containing solution channels, fissures, faults, and sink holes in very porous formations, like coarse gravel, and in formations shattered by blasting operations.

Casing, curbing, collecting piping, and galleries constructed of wood, sheet metal, riveted steel or slip joint pipe, brick, porous concrete, and vitrified clay or concrete pipe with open joints are generally unsatisfactory. Riveted pipe may leak along seams or through rivet holes. The type of well in sand in which coarse gravel is fed in around a concrete casing to increase the yield is subject to similar vertical contamination through the gravel unless properly protected.

EPIDEMICS: Shallow wells: Assembly of Old Salem Chautauqua, Ill.; Healdsburg, Calif ; Centralia, Wash.; Brunswick, Mo.; Stonewall, Okla.; Pawhuska, Okla. Deep wells: Jonesboro, Tex ; Rockville, Md ; Monroe, Mich,; Monett, Mo.; Miller, Mo., school.

SAFEGUARDS: A water-tight outside casing or curbing should be installed, extending deep enough to prevent contaminated surface or shallow ground water or other pollution from entering the well through such strata. The bottom of the casing or curbing should be effectively sealed into a solid formation and thoroughly tested to make certain that contaminated water on the outside of the casing can not enter the well

Drilled wells.—Screw-joint steel or wrought-iron pipe is the standard well casing for drilled wells and can be installed water-tight tight when new. To prevent water of unsatisfactory sanitary or

mineral quality from draining down the annular space between the drill hole and the casing into the supply, a satisfactory seal should be made or installed at the bottom, such as the following:

(*a'*) Setting bottom of casing in drill cuttings of a cementing character on a shoulder in the well made by reducing the size of the drill hole

(*b'*) Driving casing into clay or shale or similar sealing formation.

(*c'*) Cement grout.

(*d'*) Lead packer.

(*e'*) Expanding rubber packer

The seal should be tested by bailing out the drill hole and making sure there is no leakage into same over a period of 48 hours. When no water has been encountered up to time of sealing, water should be run into annular space on outside of casing.

To install a casing in an old well it is usually necessary to ream out the drill hole to furnish a shoulder for the casing to seal into. Where a wall packer will make a tight joint between the bottom of the casing and drill hole, reaming is not required.

Dug or bored wells.—Concrete curbing and pipe are commonly used for these types of wells and can be made water-tight by careful selection of materials and construction. For concrete, make rich mixture, adding 4 to 8 pounds of hydrated lime per sack of cement or an approved waterproofing preparation; mix, pour, and puddle carefully. Vitrified clay or concrete pipe should be replaced with screw-joint wrought-iron casing or the joints made water-tight with an approved bituminous joint filler.

The safe vertical depth of soil in various formations is that which will effectively filter out surface bacterial pollution, and is conservatively as follows: Solid clay, 6 feet; fine sand, 12 feet, gravel, dry adobe soil, indefinite; fissured rock, no distance—water unsafe without treatment. Wells installed with a gravel wall should be protected by forcing into the space between the outside casing and well hole sufficient puddled clay to give a protective clay depth of at least 12 feet below the ground surface or any strata carrying contaminated water.

(*b*) Holes produced by corrosion in outside metal casing, above safe water-bearing stratum, are dangerous defects because they permit pollution of well water by seepage through same. The use of the outside well casing as a suction pipe, or as a discharge pipe in airlift or deep-well pumping, is a questionable practice, as leaks will develop in the casing above the static water level if the well water is corrosive.

EPIDEMICS. Abbot, Hamilton, Tex.; pollution due to this defect has occurred at Savannah, Ga., Whitewater, Wis., St. Francois County, Mo. (private wells), Carl Junction, Mo.

SAFEGUARDS: Corrosion of a casing can be prevented by installing a shell of cement grout around same, or reduced by using cast-iron or best grade strictly wrought-iron pipe with a double coating of bituminous material. At least a 2-inch annular opening between the casing couplings and drill hole is necessary to permit the installation of a suitable cement shell around the casing. This opening can be filled with cement grout through a 1¼-inch pipe, using a tank pump. In the case of an old well, a corroded casing must be removed and the drill hole must be reamed to the proper size to allow for the cement shell. Another method, which reduces the size of the well, is to install a smaller casing of light material inside the old one to furnish an inside form for the cement shell.

Where a well is to be pumped by a suction, air-lift, or deep-well pump the safe practice is to install a separate suction or discharge pipe inside the well casing rather than to use the outside well casing for this purpose

Frequent laboratory tests should be made of all water supplies, even though well safeguarded, and purification provided if tests show its desirability

SPRINGS

Contrary to the popular belief that nothing is purer than a clear, cold, spring supply, contamination of springs is found to be general in many sections of the country from one or both of the following defects:

(7) Inadequate surface protection. Failure properly to curb many springs results in the washing of surface water directly into them during rains. Failure to cover the spring reservoir or to maintain the overflow level above high-water level in an adjacent watercourse often results in flooding or backing up of surface water directly into the spring.

EPIDEMICS: Walnutport, Pa.; Straight Creek, Ky.; Spring Township, Center County, Pa.; serious pollution at Locust Grove, Salina, Spavinaw, Okla ; Cassville, Mo

SAFEGUARDS: A tight concrete curbing and top to the spring reservoir should be installed, with overflow above back-water level. All openings should be protected and locked, similar to storage reservoirs, to prevent access of animals or persons.

(8) Surface water or pollution reaching water-bearing strata. Springs in a country underlaid with limestone usually receive water of recent surface origin immediately following rains This is evidenced by the increased flow and milkiness or turbidity of the water. In many instances sink-holes and streams have been found to be connected directly to springs through solution channels in the limestone or a coarse gravel stratum. Water from springs in other

ground formations should also be regarded with suspicion. Even where the water is clear at all times, the quality of a spring supply is doubtful and should be checked by frequent bacteriological analyses

EPIDEMICS: Adairville, Harlan, and Versailles, Ky; Pierce City, Palmyra, and Springfield, Mo; serious pollution at Mount Vernon, Mo., Martinsburg, W. Va., Elizabethtown, and Russellville, Ky.

SAFEGUARDS. Adequate purification or treatment to fit the particular circumstances. Water from springs which becomes turbid should receive the same treatment as a surface water, namely, coagulation and settling, filtration and chlorination Some supplies may be safeguarded by careful chlorination, with sufficient storage capacity in a reservoir to supply clear water during a brief period of turbid flow. Spring supplies which are clear at all times may often require disinfection

MINE WATER

Many mines furnish water for municipal supplies Defects encountered include the following:

(9) Use of mine water without treatment, from portions of a mine being worked Very few mines are equipped with sanitary toilets, with the result that the mine water is badly contaminated with bowel discharges

Serious pollution occurred from this defect at Flat River, Mo.

SAFEGUARD: Adequate purification or treatment; coagulation, filtration, chlorination Due to the consistently low turbidity of mine water, pressure filters with a brief period of coagulation will often suffice.

(10) Flooding of special water supply drifts with general mine drainage Safe supplies are often obtained from isolated unused drifts which are closed off from the rest of the mine by suitable bulkheads Unless this bulkhead is water-tight, the drift is sometimes flooded with general mine drainage due to shutdown to repair pumps, etc., with resulting contamination of the normally safe supply.

SAFEGUARD: A water-tight concrete bulkhead should be constructed, providing water-tight manhole opening if one is necessary.

INFILTRATION GALLERIES

(11) Use of water from the majority of such supplies without treatment. Where the stratum is fine sand and the distance of water travel sufficient, safe water is obtained However, in many instances, water travels rapidly from a stream or other surface source through a stratum of gravel or a short distance through sand with fair to excellent removal of turbidity, but with unreliable bacterial removal. Further, the flooding of the infiltration well or gal-

lery usually changes the direction of flow, and while the horizontal distance may effect excellent bacterial removal the vertical distance is usually so short that the water reaching the gallery will not be purified.

Pollution due to this defect occurred at Des Moines, Iowa, and Austin, Tex.

SAFEGUARD: Adequate purification or treatment to fit the circumstances.

CONCLUSION

Experience indicates that there are many sanitary defects in connection with ground-water supplies which have in the past caused the intermittent infection of otherwise safe supplies, resulting in a great many serious epidemics with a large amount of sickness and loss of life The most common of these defects, together with safeguards which have been found effective, have been detailed in an effort to summarize past experience as a guide to future practice

In many instances difficulty in adequately safeguarding a ground-water supply amply justifies the continuous disinfection of the water as insurance against intermittent slight contamination. In other instances, complete purification is required, as with a surface supply.

With a clear understanding of the experience of the past the correction of sanitary defects on existing supplies, before the combination of circumstances arises which causes the infection of a supply and a resulting epidemic, is a matter of thoroughness of the field investigation and securing the necessary improvements by the responsible authorities. To prevent these same sanitary defects on future installations requires full understanding of them by city officials, designing engineers, well drillers, pumping equipment manufacturers, erectors, and construction men. The approval of plans controls this in a measure, but such plans are often changed in construction, so that a final inspection of all new construction work is necessary to make sure that some essential safeguard has not been left out by a careless erector.

Agreement on a code of principles on sanitary control in the development of ground-water supplies and regulations for the installation of well-pumping machinery would be welcomed by engineers, manufacturers, and contractors. The principal manufacturers of deep-well pumping equipment have already agreed to the "suggested regulations" submitted, have prepared a special erection drawing, and are favorable to furnishing a sanitary well-top seal to conform to these requirements if regulations are adopted.

Code of Principles on Sanitary Control in the Development of Ground-water Supplies

GENERAL

1. Sources of ground-water supplies should be located so as to prevent their contamination by surface drainage, flooding at times of high water, and by pollution resulting from proximity to sewers, privy vaults, cesspools, sewage wells, other leaching devices for sewage, streams, abandoned uncapped wells, sink holes, etc

2 Suction and gravity piping should be constructed with water-tight material and joint, preferably cast iron and never sewer pipe. These lines should be located at a safe distance from sources of pollution and tested frequently to determine their tightness

3 Collecting or storage reservoirs and suction wells should be carefully located, of waterproof construction, and covered. All manholes, vents, and overflow openings should be properly protected from dust, small animals, and willful pollution.

4. All connections between a safe source of supply and a polluted water supply should be effectively eliminated

WELLS

5. Well supplies should be protected from contamination at the surface by the following safeguards:

(*a*) A well pit or subground level pump room should be avoided wherever practicable, and the pumps installed on a pump-room floor located above the surrounding ground level.

(*b*) If conditions necessitate the installation of a well pit or subground level pump room, the floor and walls should be made water-tight and a drain to an open outlet (under no condition connected to a sewer), or a sump and automatic ejector, should be provided to remove the waste water.

(*c*) The outside casing or curbing of wells should be extended above the level of the ground or floor of the pump room or pit and a water-tight connection installed to close the annular opening between the well casing and pump column or drop pipe. Dug wells should be provided with a water-tight cover, and the pump pipe, manhole, and other openings should be properly protected so as to prevent waste water or other contaminating material from entering the well. Pumping equipment should not be installed in the well in a manner requiring entrance of an attendant.

(*d*) On air-lift pumping systems the air inlet should be properly located and protected to minimize the entrance of dust and other contaminating material.

6. Well supplies should be protected from underground contamination by the following safeguards:

(*a*) A water-tight outside casing or curbing should be installed, extending deep enough to prevent contaminated surface or shallow ground water or other pollution from entering the well through strata such as coarse gravel and limestone containing fissures, openings, and solution channels The bottom of the casing or curbing should be effectively sealed into a solid formation and thoroughly tested to make certain that contaminated water on the outside of the casing can not enter the well.

(*b*) Wells installed with a gravel wall should be protected by forcing into the space between the outside casing and well hole sufficient puddled clay to give a protective clay depth of at least 12 feet below the ground surface or any strata carrying contaminated water.

(*c*) Where the water is known to be or suspected of being corrosive, a metal well casing should be protected by providing a shell of cement grout, at least 2 inches thick around same An alternate method, suitable in some instances, is the use of a casing consisting of cast-iron or best grade strictly wrought-iron pipe with a double coating of bituminous material

(*d*) A separate suction or discharge pipe should be installed inside a well casing in all instances, whether the well is to be pumped by suction, air-lift, or deep-well pump.

7 Continuous purification or treatment should be provided to suit the circumstances where wells are not provided with the required sanitary safeguards as outlined above or where bacteriological or chemical tests or other conditions indicate that contamination is reaching the water-bearing strata.

SPRINGS

8 Springs should be protected from surface contamination by a waterproof concrete curbing and top. Springs which show analytical or field evidence of underground contamination with surface water or sewage should be effectively purified or treated.

MINE WATER

9. Water from mines subject to contamination or pollution requires adequate purification or treatment to make a safe supply. Special water-supply drifts located in mines should be protected from flooding and drainage from working shafts and drifts

INFILTRATION GALLERIES

10. Water from infiltration galleries should receive suitable purification or treatment unless located and operated so that satisfactory bacterial removal is secured.

APPENDIX C

Suggested Regulations Covering the Installation of Well-pumping Machinery

A. The use of a well-pit or subground-level pump room shall be avoided ~~wherever~~ practicable on account of the possibility of stoppage of the drain or ejector and neglect to replace the well-top seal after making repairs.

B. Where the pump head is installed without a pit—

1 The pump head shall be installed on a concrete base of sufficient height to permit the outside casing to extend at least 4 inches above the pump-room floor and to enable the installation of a suitable connection as under B–2.

2. The annular opening between the outside casing and pump column shall be closed by means of a suitable water-tight connection which will effectually prevent waste water, oil, or other contaminating material from entering the well.

C Where the pump head is installed with a pit or in a pump room below the ground level—

1 The sides and bottom of the pit or pump room below the ground level shall be constructed of water-tight concrete. It is preferable that the pit be left uncovered, surrounded by a railing, to permit easy inspection by the pump operator.

2 The annular opening between the outside casing and pump column shall be closed by means of a water-tight connection capable of withstanding for 24 hours without leakage, the water pressure resulting from complete filling of the pit with water The types of connections approved are given below in order of preference·

(*a*) An all-flanged or threaded connection.

(*b*) A stuffing-box connection.

(c) Metal to grouted cement connection with suitable gasket (not rubber), to be used only when joint carries weight of pump column and the pump head is rigidly supported to prevent vibration

Any vents provided for the well shall be extended by a pipe with screw or flange connections to a point above the floor level A return ell shall be screwed on the upper end of this pipe and screened.

3. Drainage shall be provided for the pump pit or pump room by one of the following methods:

(a) By means of a drain, consisting of a sewer pipe not less than 6 inches in diameter, with cemented joints, installed in a straight line and on an even grade of not less than 0 6 foot per 100 feet, with a concrete bulkhead at the outlet to insure an open discharge at all times; provided that under no conditions shall this drain receive sewage or be connected to a sewer and that the bottom of the pit so drained is above the high-water level in any adjacent watercourse

(b) By means of a pump or ejector drawing from a sump of not less than 12 cubic feet capacity situated so as to collect all waste water This pump or ejector should operate automatically or be connected to some moving part of the pump head so as to operate continuously with this pump This pump shall discharge above the pump-room floor level into a suitable drain at a point safely removed from the pump pit and pump room.

4. The bottom of the pit or pump room shall be sloped away from the top of the well casing toward the drain or sump with sufficient grade to insure ready flow At least 6 inches difference in elevation shall be provided between top of the well casing and high-water level in the sump.

THE DECREASE IN THE DEATH RATE AS A MEASURE OF PUBLIC-HEALTH WORK

Prof. C. Pirquet, of Vienna, has made a study of the declining death rate of England in an article appearing in the Monthly Epidemiological Report of the health section of the League of Nations for September 15, 1926 (fifth year, No 9) The following three paragraphs and table are quoted from this article as being of interest to all persons engaged in public-health work:

If we wish to form an exact idea of the progress made in connection with public health, we can scarcely find better evidence than that supplied by the English mortality statistics, which have been kept on uniform principles since 1838 and are published in the Statistical Review of the registrar general.

The figures indicated in the following table show the number of deaths in a calendar year per 10,000 persons of the corresponding age group living in that year.

Death rate according to age groups in the respective decades, 1841–1920

[Number of deaths per 10,000 per calendar year and age]

	0–5	5–10	10–15	15–20	20–25	25–35
1841–1850	660	90	53	75	93	103
1851–1860	676	85	50	70	87	98
1861–1870	[illegible]	80	45	64	82	98
1871–1880	634	65	37	51	71	90
1881–1890	568	53	30	44	56	76
1891–1900	577	43	25	37	47	64
1901–1910	460	36	21	30	38	51
1911–1920	[illegible]	35	22	(15–45)54		
	35–45	**45–55**	**55–65**	**65–75**	**75–85**	**Over 85**
1841–1850	129	170	293	636	1,415	3,010
1851–1860	123	165	289	617	1,399	2,965
1861–1870	127	174	304	628	1,404	2,966
1871–1880	127	178	316	630	1,422	3,083
1881–1890	115	171	314	650	1,376	2,840
1891–1900	105	168	315	650	1,372	2,708
1901–1910	83	143	281	568	1,272	2,608
1911–1920	(15–45)54	130	259	573	1,320	2,668

If we take the figure at the head of column 2, 90 indicates that from 1841 to 1850, on an average, 90 children between the ages of 5 and 10 per 10,000 died in each calendar year. The figure at the bottom of the second column, 35, indicates that from 1911 to 1920 only 35 deaths per 10,000 children between 5 and 10 occurred. The difference between these figures can be ascribed to the progress made in public health.

COURT DECISIONS RELATING TO PUBLIC HEALTH

Establishment and maintenance of isolation hospital in residence district not enjoined.—(California Supreme Court; Jardine *v* City of Pasadena, 248 p. 225; decided July 1, 1926.) The establishment and maintenance by the city of Pasadena of an isolation hospital in a residential district were sought to be enjoined by owners of property adjacent to the block selected as the hospital site. The court decided adversely, however, to the plaintiffs and refused to grant an injunction.

Damages for tuberculosis contracted because of working conditions denied.—(New York Supreme Court, Appellate Division; Wager *v*. White Star Candy Co., Inc., 217 N. Y. S. 173; decided July 2, 1926.) The plaintiff brought action to recover damages for illness from tuberculosis. The disease was alleged to have been contracted because of the insanitary conditions under which she worked. The court dismissed the complaint on the ground that the plaintiff, being fully aware of the conditions under which she worked and having continued in the employment for several months in spite of such knowledge, assumed the risk attendant upon her remaining in the employment.

Injunction to restrain city in its method of garbage disposal refused —(Louisiana Supreme Court; Gibson *v.* City of Baton Rouge, 109 So. 339; decided June 28, 1926) In a suit against the city of Baton Rouge by persons residing in the suburbs, complaint was made that the system of garbage disposal was offensive to their senses of sight, smell, and hearing, and that it interfered with their comfort and jeopardized their health. The court refused to issue an injunction restraining the city from disposing of its garbage by the only means and in the only way which seemed available, but also stated in the opinion that "we do not decide, and it is not now necessary for us to decide, that plaintiffs are without a remedy for such damages as they may suffer after due demand upon the city for the suppression of the noxious sights, smells, and noises, surrounding the garbage disposal plant herein complained of, and after reasonable time given in which to suppress them "

Certain product held not within act relating to butter substitutes.—(Illinois Appellate Court, First District; People *v* Waskow Butter Company, 239 Ill. App 604; decided March 2, 1926.) An Illinois law prohibited the coloring of "any substance designed as a substitute for butter, whereby such substitute * * * shall be made to resemble butter, the product of the dairy " The article under consideration in this case was made from coconut and peanut oils, salt, and harmless yellow coloring matter, and was not injurious to health It was sold in 1-pound, triangular paper packages, and was labeled as being a nut product prepared for cooking and baking and as containing coloring matter. It was distinguishable from butter at a distance of about 10 feet, and was not suitable for table use, and had a different odor and taste from butter. The court held that the act was not applicable to the product in question, stating as follows in the opinion:

A reasonable construction of the words of the Illinois act, "any substance designed as a substitute for butter," means a substance designed as a substitute for butter in all the usual and customary uses of butter. The act could not reasonably apply to a substance which can not be used for the largest and most usual use of butter—namely, as a spread on bread. A reasonable construction must take into account butter's major use and not alone its use for cooking We construe the language of the statute as nonapplicable to the nut product in question.

* * * * * * *

The evidence before us shows that the nut product contains no dairy products and there is no pretense in any of the advertising that it does It is represented only as a cooking compound, and it is not advertised as butter or as a substitute for butter, and the word "butter" is not used in the advertising. It is conceded by the plaintiff that the product was not designed to deceive or to be sold as butter or for butter. As no element of deception is alleged, proven or claimed, we hold that the prohibition of this article is not within the intent of the act

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for September, 1926

The accompanying table is taken from the Statistical Bulletin of the Metropolitan Life Insurance Co for October, 1926, and presents the mortality experience of the industrial insurance department of the company for the month of September, 1926, as compared with August, 1926, September, 1925, and the year 1925. The rates are based on the records of approximately 17,000,000 insured persons in the industrial populations of the United States and Canada.

The bulletin states.

Health conditions in September among the industrial populations of the United States and Canada showed a decided improvement as compared with the same month of 1925 The death rate this year was 8 1 per 1,000, which marks an improvement of approximately 6 per cent over the figure for September, 1925 (8 6) The September rate was slightly higher, as compared with August of this year, but the figures for both months are lower than the average for recent years

The advent of the fall season has been accompanied by the usual rise in the typhoid fever death rate, which almost doubled as compared with August The September figure, nevertheless, is lower than for the same month last year, and the mortality record for typhoid fever thus far in 1926 shows that the downward trend of the death rate, which has been prevailing for a long series of years, is still in evidence

Whooping cough had a higher death rate in September than the other three principal diseases of childhood—diphtheria, scarlet fever, and measles. It was the only one of these four diseases to show an above-average September death rate

The influenza death rate in September was only 4.6 per 100,000, which is slightly below the August figure and considerably below the rate for September, 1925. The mortality from pneumonia was virtually identical with that recorded for August, and considerably lower than the figure for September of last year. There were absolutely no signs, in September, pointing to unusual prevalence of influenza

Two other items of primary public health interest, namely, diarrheal diseases, and conditions incidental to pregnancy and childbirth, showed very gratifying declines as compared with September a year ago

In no single instance did any disease show a substantial increase as compared with last year.

During September there were 132 suicides, corresponding to a death rate of 9 per 100,000 This, with a single exception (May, 1923), is the highest suicide death rate recorded for any month among Metropolitan industrial policyholders. Automobile fatalities numbered 301, with a death rate of 20 5 per 100,000. This marks a high point for the months so far in 1926, and is, in fact, the highest rate recorded for any month since October, 1925.

Death rates (annual basis) for principal causes per 100,000 lives exposed, August and September, 1926, and September and year 1925

[Industrial department, Metropolitan Life Insurance Co]

Causes of death	Rate per 100,000 lives exposed [1]			
	Sept 1926	Aug, 1926	Sept, 1925	Year 1925
Total, all causes	814.2	785.8	859.9	907.5
Typhoid fever	8.4	4.8	8.8	4.6

PUBLIC HEALTH ENGINEERING ABSTRACTS

Practical Aspects of Plague in Wild Rodents. Wu Lien Teh. League of Nations' Health Organization, Geneva, 1925 October 7. C. H. 360, 19 pp. (37 refs.) (Abstracted by J. F. C. H.) From *Bulletin of Hygiene*, vol. 1, No 4, April, 1926, pp. 310–311.

"The author reviews available knowledge as to the mode of transmission of plague from one animal to another, from one settlement of animals to another, and from the various animals to man. He discusses the respective problems of California (ground squirrels), South Africa (gerbilles), South Russia (sisels or spermophiles and mice), and Transbaikalia and Mongolia (tarabagans). The failure of costly attempts at extermination of some of these animals is emphasized. Stress is laid upon the economic importance of the

tarabagan, which does not harm crops and is itself a chief means of sustenance to the population of a wide area He shows how it is only in the hunting and subsequent handling of tarabagans that risk of plague infection occurs, and how the prohibition of such hunting led to illicit trade and increased risk, and gives an outline of the measures of control proposed now that the regulation of the tarabagan trade has replaced prohibition. An appendix gives a revised list of rodents, other than the domestic rat and mouse, known to suffer from spontaneous plague (Cf. Kauntze's list for South Africa. *Bulletin of Hygiene*, vol 1, p. 66.)"

The Natural Enemies of Rats; Their Possibilities in Plague Prevention. G H. Goldfinch, with note by W H. Kauntze *Kenya M J*, 1925, vol 2, pp 225–234 (Abstracted by J F. C H.) From *Bulletin of Hygiene*, vol 1, No 4, April, 1926, p. 311.

"Stimulated by an article by Dr W H. Kauntze (*Bulletin of Hygiene*, vol 1, p 66), the author contributes an interesting but speculative paper in which a large number of different animals are considered as natural enemies of rats in Kenya Colony. He thinks the mole rat likely to be the most dangerous rodent as regards plague in that colony, and, among the many enemies of rodents considered, appears to favor the European little owl and the Indian mongoose for introduction to Kenya.

"Kauntze adds a note in which he points out that there are as yet insufficient facts upon which to base plans for Kenya, but that in South Africa the mole rat seems to escape plague. He has doubts, too, as to the ability of natural enemies to prevent the multiplication anew of rodents practically wiped out by plague, and points out that while the mongoose is perhaps more or less immune to plague he may yet spread it by means of his numerous fleas.

"(Neither Kauntze nor Goldfinch indicates the zoological position of the rodent spoken of as a 'mole rat.' Indeed, the latter says he can not remember whether it is a true rat or a vole. The 'mole rat' is not mentioned by that name in the booklet 'Rodents,' published by the health department of South Africa, but Wu Lien Teh (see summary on p. 310) quotes Mitchell as having described the 'mole rat *Cryptomys*' as plague infected)"

Earlier determination of bacterium coli. C. J. Lauter, *Water Works*, vol. 65, No. 9, September, 1926, pp. 451–453 (Abstract by E. A. Reinke.)

Research work at Washington filtration plant on use of brilliant green bile medium shows possibility of getting *B. coli* test results one or two days earlier than by use of present standard methods. A much higher percentage of confirmatives was obtained than with lactose. Samples of chlorinated effluent gave gas in lactose, but did not confirm and would not grow on bile Tables are given.

Night-soil disposal in unsewered areas. Anon The Sanitary Engineer Commission of Public Health, State of Victoria, Australia. *Health Bulletin* No. 4, October–December, 1925, pp 110–113. (Abstract by W. H. Wendler)

Due to the lack of constant water supply with adequate pressure, and also the scattered positions of the houses in rural communities, a sewerage system is out of the question, and other means of night-soil disposal must be relied upon Such means are fixed and movable receptacles, cesspools, and chemical closets. With all of these a great risk is taken of contaminating the local wells, streams, and other sources of water supply With these different methods of disposal great care must be taken with regard to flies, odors, and other conditions causing a nuisance

The most generally adopted mode of night-soil disposal is by earth burial. It is an accepted sanitary principle that putrescible refuse should be disposed of by shallow burial in soil whose upper layer is well drained, light, friable, sandy loam, capable under cultivation of supporting vegetation and in which nitrifying organisms can reside and flourish. It is not desirable to disinfect the night soil that is disposed of in this manner, as the germicidal matter destroys the nitrifying organisms. It is also undesirable to deposit night soil below a depth of 2 or 3 feet, as nitrification is believed to be confined to this depth. Air is of vital importance in the operation of the oxidizing organisms.

Experiments have shown that organic matter buried deep in the soil develops intense putrefaction and may remain in a potentially offensive condition for years. The size and arrangement of the trenches, in the case of municipal depots, should be under the supervision of the council's engineer

Ice cream as a cause of epidemics. Frederick W. Fabian, Associated Professor of Bacteriology and Hygiene, Michigan Agricultural Experiment Station, East Lansing, Mich *American Journal of Public Health,* vol. 16, No. 9, September, 1926, pp. 873–879. (Abstract by R. E. Irwin.)

To-day ice cream has become such a common article of diet that it should be taken into account by the epidemiologist when tracing an epidemic. The public-health official, if he has not already done so, will in the very near future need to regulate its sanitary quality.

References are given showing research work proving the very low temperatures at which pathogenic bacteria live in ice cream. Twenty-six epidemics traceable to ice cream are cited and references given.

The summary states: "It has been demonstrated by several investigators that exposure to the temperatures used in freezing and storing ice cream can not be relied upon to kill all pathogenic bacteria that may be present.

Numerous outbreaks of disease, such as typhoid fever, diphtheria, scarlet fever, diarrhea, and intestinal disturbances have been definitely traced to contaminated ice cream. It is believed that the same sanitary precautions should be taken by health officers, State and city boards of health, in protecting the ice-cream supply as are taken with the milk supply.

Three safeguards are suggested: (1) Pasteurizing the ice-cream mix at 150° F. for 30 minutes; (2) establishing a bacteriological standard 100,000 bacteria (colonies) per gram; (3) regular sanitary inspection of ice-cream plants"

The Pasteurization of milk and cream. J R. Corry. *Rhodesia Agric J*, 1925, vol 22, pp 940–948, 5 figs. (Abstracted by W. G. Savage) *Bulletin of Hygiene*, vol 1, No 4, April, 1926, p 279.

"Gives a useful description of the two methods of Pasteurization—i. e., the continuous process and the intermittent process, with illustration of common types of apparatus The author prefers the first process (often called 'flash' Pasteurization) as more practical where large amounts of milk and cream are handled, while in favor of the vat or intermittent process are the simplicity of construction, ease of operation, and economical working (The relative bacterial efficiency of the two processes is not discussed) He mentions that Pasteurization in bottles is rapidly gaining favor with dairies

"The author realizes the objection to Pasteurization in that it encourages careless methods of production and handling. While condemning such methods, he does so on bacteriological grounds which are not in accordance with English experience In his view the Pasteurization destroys the acid-producing bacteria, while the more harmful and more resistant types remain, so that dirty Pasteurized milk is still dangerous to the consumer. (Many putrefactive bacilli are destroyed at Pasteurization temperatures.)

"Pasteurization in the butter and cheese industry is strongly advocated, in that it makes possible the manufacture of a uniform product, it improves the keeping qualities of the article, it improves the flavor and aroma, and it destroys pathogenic organisms, making the product a safe and healthful food The author again emphasizes that even with Pasteurization cleanliness in the production of the raw material is essential."

An outbreak of anthrax contracted from handling infected beef. A. K. Mukerji. *Indian M Gaz.*, 1926, vol. 61, 22, 1 fig. (Abstracted by C. O. Stallybrass) From *Bulletin of Hygiene*, vol. 1, No. 5, May, 1926, p 349

"Seven persons in a village near Tipperah who had taken part in killing a cow, or in dressing the meat, were attacked with malignant pustules in various situations. Despite the absence of precautions,

no spread occurred to others who had not handled the meat. Four of the cases proved fatal."

Milk Pasteurization in Illinois in 1926. Lewis Shere, Milk Sanitarian, and Harry F Ferguson, Chief Sanitary Engineer, Illinois State Department of Health *Illinois Health News*, vol. 12, No. 9, September, 1926, pp. 317–333. (Abstract by I. W. Mendelsohn.)

The 1925 legislature enacted a milk Pasteurization-plant law with the following features: "(1) Pasteurization is defined as the process of heating milk or milk products to a temperature of at least 142° F. and holding at such temperature for not less than 30 minutes; (2) operators of Pasteurization plants shall apply to the State department of public health for a certificate of approval; (3) the State department of public health shall prepare minimum requirements for the construction, equipment, operation, and maintenance of Pasteurization plants; (4) certain provisions for the sanitary quality of the raw milk which is to be Pasteurized are made; (5) Pasteurization plants located in and supplying milk exclusively to cities having populations over 500,000 are exempted This actually exempts only Chicago and was made at the request of representatives of Chicago because it was considered that the city health department would undertake equivalent sanitary control under existing or new ordinances."

Some of the principal requirements adopted by the department are given. Preliminary inspections were made by the division of sanitary engineering in accordance with the law for the purpose of determining the conditions at the plants in regard to the construction, equipment, and operation, and especially to inform the owners wherein their plants did not comply with the law and the minimum requirements. These inspections were completed June 1, 1926, and showed: (1) In Illinois an estimated average of three-fourths of the milk is Pasteurized in cities with a population of 30,000 or over, exclusive of Chicago. In Chicago about 99 per cent of the milk supply is Pasteurized; (2) Pasteurization is more general in the larger than the smaller cities of Illinois. All of the cities having a population ranging from 25,000 to 100,000, and 85 per cent of the cities with a population of 10,000 to 25,000 have Pasteurization plants, whereas Pasteurized milk is available in only 2.6 per cent and 19 per cent of the cities with populations of less than 1,000 and between 1,000 and 5,000, respectively; (3) summary of number and volume of Pasteurization plants: Pasteurization plants, 306; cities having Pasteurization plants, 140; gallons Pasteurized daily (average), 337,778; total commercial Pasteurizers in milk plants, 449; average daily plant volume (gallons), 1,080; largest plant, daily volume (gallons), 24,000; smallest plant, daily volume (gallons), 25.

Illustrations are given of sanitary and insanitary types of equipment found, also table summarizing data regarding the investigation.

The more important problems requiring attention are: (1) Proper recording devices; (2) elimination of leaky valves; and (3) overcoming foaming and splashing.

The legal aspects of the stream pollution problem.—John H. Fertig, Pennsylvania Legislative Bureau. *American Journal of Public Health*, vol. 16, No. 8, August 1926, pp. 782–787. (Abstract by John H. O'Neill.)

The common law of the several States on the subject of stream pollution is to be found in many hundreds of adjudicated cases, and the whole intricate legal structure which has been developed by these cases rests in the end upon a few simple principles which are rather definitely settled.

The American common-law doctrine was derived from the French Code Napoleon rather than from the English common law. The original doctrine may be stated—that each riparian owner has the right to have a stream come down to him with its quality unimpaired and its quantity undiminished. At the present time this is an extreme statement and can not be literally accepted. There is not a property right in flowing water, it is not the subject of ownership but is subject simply to a reasonable, or, as it is usually called, a natural, use by the owner through whose land it flows. On the other hand, the right to use flowing water is not a mere easement, but is inseparably annexed to the soil and must be regarded as a property right.

Among the many cases which point out what is to be considered a natural and reasonable use of a stream are found as most common ones, domestic supply, swimming, pasturing of cattle, cultivation of lands, drainage of swamps, and the collection of surface water and its discharge into the water course which is the natural outlet. The natural use of a water course can not be supported if its use becomes immoderate. The distinction between that which is and that which is not a natural use is entirely a question of degree, and it is difficult to define the precise limits which separate the reasonable and permitted use of a stream from its wrongful application. The uniform customs of the community for generations may be of some significance in determining what is a reasonable or natural use of a stream, but is not conclusive upon the question. There are cases in which rights to pollute streams have been gained by custom or prescription and can be maintained as against riparian owners, but not as against the public.

There is need for the establishment of a firm and definite State policy with regard to pollution, for the adoption by the State of just and correct principles of legislation, and for more extensive cooperation between industry and the State.

The article contains an extensive list of references to court decisions illustrative of the principles presented.

DEATHS DURING WEEK ENDED NOVEMBER 13, 1926

Summary of information received by telegraph from industrial insurance companies for week ended November 13, 1926, and corresponding week of 1925 (From the Weekly Health Index, November 17, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Nov 13, 1926	Corresponding week, 1925
Policies in force	65, 619, 100	62, 053, 222
Number of death claims	11, 216	11, 502
Death claims per 1,000 policies in force, annual rate	8 9	9 7

Deaths from all causes in certain large cities of the United States during the week ended November 13, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925. (From the Weekly Health Index, November 17, 1926, issued by the Bureau of the Census, Department of Commerce)

[4] Deaths for week ended Friday, Nov 12, 1926

[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31, Baltimore, 15; Birmingham, 39, Dallas, 15, Fort Worth, 14, Houston, 25, Indianapolis, 11; Kansas City, Kans, 14; Louisville, 17, Memphis, 38, Nashville, 30; New Orleans, 26, Norfolk, 38, Richmond, 32, and Washington, D. C, 25

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended November 20, 1926

ALABAMA	Cases
Chicken pox	6
Diphtheria	120
Influenza	69
Lethargic encephalitis	3
Malaria	54

[1] Including paratyphoid fever.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended November 6, 1926, 39 States reported 2,459 cases of diphtheria. For the week ended November 7, 1925, the same States reported 2,009 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,400,000, reported 1,308 cases of diphtheria for the week ended November 6, 1926. Last year for the corresponding week they reported 923 cases. The estimated expectancy for these cities was 1,345 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-seven States reported 2,371 cases of measles for the week ended November 6, 1926, and 1,740 cases of this disease for the week ended November 7, 1925. One hundred cities reported 474 cases of measles for the week this year, and 856 cases last year.

Poliomyelitis.—The health officers of 40 States reported 61 cases of poliomyelitis for the week ended November 6, 1926 The same States reported 117 cases for the week ended November 7, 1925

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-nine States—this year, 2,885 cases; last year, 2,500 cases; 100 cities—this year, 1,103 cases; last year, 936 cases, estimated expectancy, 846 cases.

Smallpox.—For the week ended November 6, 1926, 39 States reported 246 cases of smallpox. Last year for the corresponding week they reported 265 cases. One hundred cities reported smallpox for the week as follows: 1926, 15 cases; 1925, 52 cases; estimated expectancy, 35 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Seven hundred and fifty-five cases of typhoid fever were reported for the week ended November 6, 1926, by 39 States. For the corresponding week of 1925 the same States reported 853 cases of this disease One hundred cities reported 140 cases of typhoid fever for the week this year and 155 cases for the corresponding week last year. The estimated expectancy for these cities was 113 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,700,000, as follows: 1926, 634 deaths; 1925, 820 deaths.

City reports for week ended November 6, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

[2] Typhus fever; 1 case at Atlanta, Ga

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended November 6, 1926, compared with those for a like period ended November 7, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities

reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, October 3 to November 6, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

DIPHTHERIA CASE RATES

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week.

ASIA

Arabia.—Aden, Jeddah, Kamaran, Perim.

Iraq.—Basrah.

Persia.—Mohammerah, Bender-Abbas, Bushire.

British India.—Chittagong, Cochin, Vizagapatam, Negapatam.

Ceylon.—Colombo.

Federated Malay States.—Port Swettenham.

Straits Settlements.—Singapore, Penang.

Dutch East Indies.—Cheribon, Samarang, Batavia, Sabang, Makassar, Banjermasin, Palembang, Menado, Pontianak, Balik-Papan.

Sarawak.—Kuching.

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.

Portuguese Timor.—Dilly.

French Indo-China.—Saigon and Cholon, Turane, Haiphong.

China.—Hongkong.

Formosa.—Keelung.

Japan.—Yokohama, Osaka, Nagasaki, Kobe, Niigata, Tsuruga, Hakodate, Shimonoseki.

Korea.—Chemulpo, Fusan.

Manchuria.—Mukden, Changchun, Harbin, Antung.

Kwantung.—Port Arthur, Dairen.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.

New Guinea.—Port Moresby.

New Britain Mandated Territory.—Rabaul.

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.

New Caledonia.—Noumea.

Fiji.—Suva.

Hawaii.—Honolulu.

Society Islands.—Papeete.

AFRICA

Egypt.—Port Said, Suez, Alexandria.

Anglo-Egyptian Sudan.—Port Sudan, Suakin.

Eritrea.—Massaua.

French Somaliland.—Jibuti.

British Somaliland.—Berbera.

Italian Somaliland.—Mogadiscio.

Kenya.—Mombasa.

Zanzibar.—Zanzibar.

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria.

Portuguese East Africa.—Mozambique, Beira, Lourenco, Marques.

Union of South Africa.—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India —Calcutta.
Dutch East Indies —Samarinda, Tarakan
Philippine Islands —Manila, Iloilo, Jolo, Cebu, Zamboanga
Madagascar —Tamatave, Majunga

AZORES

Gastroenteritis—Horta—September, 1926 —During the month of September, 1926, four cases of gastroenteritis with four deaths were reported at Horta, Island of Fayal, Azores.

BRAZIL

Mortality—Leprosy—Malaria—Manaos—July 1–September 30, 1926 —During the three months ended September 30, 1926, 6 deaths from leprosy and 52 from malaria were reported at Manaos, Brazil. The total number of deaths from all causes was 233. Population, estimated, 80,949.

CANADA

Communicable diseases—Week ended October 30, 1926 —The Canadian Ministry of Health reports cases of certain communicable diseases for the week ended October 30, 1926, as follows.

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta[1]	Total
Influenza	13							13
Lethargic encephalitis						2		2
Poliomyelitis				5				5
Smallpox				30	29	6	9	74
Typhoid fever		9	5	23	2	6	9	54

[1] Report for week ended Oct 23, 1926, smallpox, 3, typhoid fever, 2

Communicable diseases—Ontario—October, 1926—Comparative.— During the month of October, 1926, communicable diseases were reported in the Province of Ontario, Canada, as follows:

Disease	1926		1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis	5	1	5	5
Chancroid	1			
Chicken pox	544		460

Gonorrhea	177		141	
Influenza		10		11
Lethargic encephalitis	7	5	2	2
Measles	383		309	
Mumps	25		103	
Pneumonia		128		165
Poliomyelitis	27	4	14	
Scarlet fever	361	1	384	6
Septic sore throat	3		4	
Smallpox	75		19	
Syphilis	173		128	
Tuberculosis	96	54	142	66
Typhoid fever	101	10	137	5
Whooping cough	304	3	247	6

Smallpox.—Smallpox was reported in eight localities, with the greatest number of cases, viz, 48, reported at Timmins.

Hospital standardization—Nova Scotia—Information dated October 27, 1926, shows that 11 hospitals in Nova Scotia have received full or conditional approval from the American College of Surgeons, which in 1918 established hospital standardization The list of hospitals in Nova Scotia which conform to the requirements shows 2 of over 100 beds, and 9 of 50 to 100 beds.

CHILE

Reorganization of Public Health Service—Under date of September 4, 1926, the reorganization of the Public Health Service of Chile was stated to include 13 local boards of health appointed and functioning, and 12 municipal sanitary districts organized and operating. There have been created 83 sanitary divisions, of which 25 were stated to be actually functioning

Teachers' correspondence courses in hygiene.—The department of sanitary education of the bureau of sanitation is stated to have organized a correspondence course in hygiene for all primary school teachers in Chile It was stated that 4,000 teachers had enrolled themselves for the course.

CHINA

Cholera — Plague — Hospitalization — Preventive measures — North Manchuria—Third quarter, 1926.—The following information was received under date of October 18, 1926, with regard to disease prevalence in North Manchuria, China, for the quarter ended September 30, 1926:

Cholera and choleraic diseases.—Cholera appeared at Harbin during the summer of 1926, the first authentic case being in a bean-cake worker reported August 5, followed by three other cases in the same group. Cases appeared in the Special Area, the greatest number reported for any one day seldom exceeding 10. The last case in the Chinese city was reported September 12 and the last in the Special Area about September 19. The number of cases admitted to hospital was: For the municipal hospital, 66 cases, with 36 deaths, Pinchiang (Plague Prevention Service), 168 cases with 29 deaths; railway hospital, 55 cases with 18 deaths. Cholera was reported in practically every large city in North Manchuria, the greatest number of cases being reported at Antung (500), and Changchun (320). Dairen had 10 cases and Newchwang 167 cases The total number of cases in North Manchuria was stated to be not much over 1,500.

The total number of cases reported in Manchuria was stated to have been one-tenth of that reported in the year 1919.

Related diseases.—Dysentery and infantile diarrhea were stated to have been unusually prevalent during the summer of 1926.

Typhoid fever—Typhoid fever prevalence was noted during the period under report

Plague—A few sporadic cases of plague, occurring in Russians, were reported in the transbaikal region The bubonic cases occurred in tarabagan hunters Two cases of pneumonic plague were reported among horse breeders at Olovianaya, an important city situated between Manchouli and Chita.

EGYPT

Plague—Western Desert Province—During the week ended October 21, 1926, four cases of plague were reported in the Western Desert Province 60 kilometers distant from Sidi Barrani

Summary—January 1–October 21, 1926.—During the period January 1 to October 21, 1926, 139 cases of plague were reported in Egypt as compared with 131 cases reported for the corresponding period of the year 1925.

JAMAICA

Smallpox (alastrim)—September 26–October 30, 1926—During the period from September 26 to October 30, 1926, 89 cases of smallpox (reported as alastrim) were notified in the Island of Jamaica, occurring in localities other than Kingston.

Other communicable diseases—During the same period other communicable diseases were reported in the island as follows:

Disease	Cases: Kingston	Cases: Other localities	Disease	Cases: Kingston	Cases: Other localities
Chicken pox	1	9	Ophthalmia		1
Diphtheria		2	Paratyphoid fever		1
Dysentery	27	19	Puerperal fever	1	2
Erysipelas	1	1	Tuberculosis	17	60
Leprosy		1	Typhoid fever	19	111

Population of island, estimated, 858,118, population of Kingston, 62,707, census

JAPAN

Cholera—Taiwan Island.—During the period September 21 to October 10, 1926, 11 cases of cholera were reported in the island of Taiwan, Japan, making a total of 16 cases occurring since September 1, 1926. The first case was stated to have arrived in the Taihoku Province from Foochow, China, through the port of Tansui.

MEXICO

Cerebrospinal meningitis—Gastroenteritis—Progreso—October 10–16, 1926.—During the week ended October 16, 1926, two deaths from cerebrospinal meningitis and two from gastroenteritis were reported

at Progreso, Yucatan, Mexico. Meningitis was stated to be of frequent occurrence as a cause of mortality in children.

Influenza.—During the same period influenza was reported present in epidemic form but not of virulent type.

PERU

Cooperation of the press in sanitary work.—According to information dated August 20, 1926, a meeting of leading editors called on that date at Lima considered the subject of the responsibility of the press in regard to the defense of public health and agreed on a program for broadcasting information in the interest of a sanitary campaign then being carried on. Especial attention was given to the need for cement foundations in house building to prevent the ingress of rats.

Inauguration of anticancer league—Lima—Information has been received under date of September 11, 1926, in regard to the inauguration by the Surgical Society of Peru, of the anticancer league for conducting a campaign against cancer in Peru. It was stated that a permanent committee had been established for the study of cancer conditions, the program of the committee to include the establishment of dispensaries for cancer treatment in various hospitals, establishment of a library of medical information on the subject of cancer, and a bureau of propaganda to distribute data as to the prevention and treatment of the disease. The program was to include the appointment of a visiting service for cancer work, special care of cancer patients in general hospitals, and the creation of a special hospital for the treatment of cancer cases.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

HEALTH STUDIES OF NEGRO CHILDREN

I. INTELLIGENCE STUDIES OF NEGRO CHILDREN IN ATLANTA, GA.

I. Introduction

By VIRGINIA TAYLOR GRAHAM, Psychologist, United States Public Health Service

During the scholastic year 1925–26 the United States Public Health Service, in cooperation with the Georgia State Board of Health and the Atlanta Board of Education, conducted a survey of the mental and physical status of the children in the negro public schools of Atlanta The psychological examinations, with which this paper is concerned, were made in five of the elementary negro schools, and include tests—group, individual, or both—of a total of 3,028 children.

In four of the schools, group tests were given to all the grades except the first, that is, to grades 2 to 6, inclusive. As group tests are more unreliable with very young children whose comprehension and cooperation it is somewhat difficult to secure in such circumstances, it was thought best to devote the time to the subjects that promised the most reliable results Consequently the data on group tests contain only 79 cases of children below grade 2, and these are from two sections of a high first grade in the same school. In the fifth school, as time did not permit the testing of all classes, the group examination was given only to the fifth and sixth grades, in order to increase the number of cases at the higher age levels.

The Otis Group Intelligence Scale [1] was used for all the group testing—the "Primary" form for the first four grades and the "Advance" for grades 5 and 6. The selection of cases for individual examinations was determined chiefly by the Otis test. As many as possible of the children who made low or doubtful scores in this scale were given individual tests; a few other special cases were referred by principals and teachers, and a group of unselected first-graders was studied, these last consisting chiefly of the children who had received physical examinations in connection with the same general survey. The individual examinations consisted of the Standford revision of the Binet-Simon tests [2] supplemented, at the discretion of the examiner, by Kohs Block Design Test,[3] the Lin-

coln Hollow Square,[4] and the Healy Construction A.[5] All of the tests were made by the writer

II. The Group Tests

In order to consider the data in their most objective form, the results are first studied in terms of crude score, that is, the total number of points made on the test. This necessitates the separation of the primary test (first four grades) from the advanced examination (here the fifth and sixth grades) Age designations in this paper always refer to the last birthday. Thus, in the 7-year group ~~are~~ included all children who have passed their seventh but have not reached their eighth birthday, and whose median age would therefore approximate 7 years 6 months

In the absence of comparable data on white children from this locality, comparison is probably best based on the figures furnished by Otis. His subjects come, he says, "from some 200 cities throughout the country "[6] When the mean scores obtained on the primary examinations of the group studied by age groups 7 to 12, inclusive, are compared with the Otis white norms[7] for the respective mid-year points (see Table 1), yearly increments in score are shown in both cases. They are appreciably larger in the case of the American white norms.

TABLE 1.—*Mean scores of Atlanta negro children on Otis primary examination compared with Otis's norms for American whites*

	Age					
	7	8	9	10	11	12
Negro	31	36	41	43	47	50
Norm	28	41	54	66	74	79
Difference[1]	3	−5	−13	−23	−27	−29

[1] Minus sign indicates that the score of negro is lower.

The increments generally decrease with age, and this is relatively more marked in the case of the group here studied. Although the mean score of the 7-year-old negroes is slightly higher than the Otis norm, at every succeeding age level the score falls progressively below the standard.

Table 2 makes a similar comparison in the case of the advanced examination.

[4] Dearborn, Walter F., Shaw, Edwin A , and Lincoln, Edward A A Series of Form Board and Performance Tests of Intelligence. Harvard Monographs in Education, Series 1, No. 4, September 1923, pp 32–33, 56–59

[6] Op. cit. p. 54.

[7] Ibid. p. 71.

TABLE 2.—*Mean scores of Atlanta negro children on Otis advanced examination compared with American white norms*

	Age				
	10	11	12	13	14
Negro	52	54	59	57	55
Norm	61	74	85	95	105
Difference	−9	−20	−26	−38	−50

Attention should be called to the fact that the relatively few 10-year-old negro children in the fifth and sixth grades—83 cases in comparison with 328 cases in the lower four grades—are obviously superior ones and, hence, do not give a fair measure of racial performance on this particular scale. At the other extreme, the 13 and 14 year olds who have not progressed beyond the sixth grade and whose scores on this test fall below that of the 12-year-olds, are just as obviously not fair representatives of negro achievement at those ages At ages below 13, where the selection is fair, the racial means of the group studied fall consistently below the white norms, the discrepancy between the two increasing with age.

In fairness to the negro children it should be noted that, while our figures for the negroes are strictly empirical, the Otis norms are partly theoretical, the curves, naturally, are somewhat straightened and points are moved in accordance with *a priori* considerations. If the actual means are computed from the Otis data [8] the figures given in Table 3 are obtained for comparison.

When these figures are compared with those in the two preceding tables, the most striking point is that Otis, in preparing his norms, has decidedly readjusted his figures for ages 10, 11, and 12 in the primary examination The norm he sets is markedly higher than his obtained mean at each of these age levels His obvious reason for so doing is because his subjects, coming as they do from the first five grades only, do not include any of the brighter children of these ages and so give a mean that is too low. The same point can, of course, be made with respect to the negro subjects, who, in the case of the primary examinations, are not drawn from grades higher than the fourth, and in the case of the advanced examination are confined to grades 5 and 6. The amount of retardation that is characteristic or normal for the races will be referred to later.

[8] Ibid, pp. 76-80.

TABLE 3.—*Comparison of mean scores of Atlanta negroes and of Otis's subjects*

	Age								
	Primary examinations						Advanced examinations		
	7	8	9	10	11	12	11	12	13
Negro	31	36	41	43	47	50	54	59	57
White	31	42	52	59	60	62	75	85	95
Difference	0	−6	−11	−16	−13	−12	−21	−26	−38

TABLE 4.—*Otis test scores, variabilities, difference from American white*

PRIMARY EXAMINATIONS, GRADES 1 to 4

Age	Atlanta negroes					American white (200 cities)					Difference from American white	
	Number of cases	Mean score	Probable error	Standard deviation of distribution	Probable error	Number of cases	Mean score	Probable error	Standard deviation of distribution	Probable error	Difference	Probable error of difference

ADVANCED EXAMINATIONS, GRADES 5 AND 6

10	83	52.23	±1 83	24 66	±1 29	2,435	76.11	±0 35	25.70	±0 25	−23 88	±1 86
11	180	54 22	±1 16	23 03	± 82	4,186	79 22	± 29	27 58	± 20	−25 00	±1 19
12	246	59 02	±1.06	24.54	± 75	3,565	77.02	± 30	26 64	±.21	−18.00	±1 10
13	222	57 43	±1 02	22 49	± 72	1,918	71.18	± 35	22.57	±.25	−13 75	±1 08
14	150	55 47	±1 47	26.62	±1 04	842	66.48	± 54	23 42	±.38	−11 01	±1 56

For the sake of ultimate fairness, a comparison may be made which probably favors the negro group. That is, for comparison only, those cases of Otis's may be taken which were in the same grades as those to which we gave the respective tests. Table 4, which gives the means and measures of variability for the subjects of this study, also gives the same data for whites who, in the case of the primary examination, are confined to the first four grades and, in the instance of the advanced examination, to the fifth and sixth grades. We are most concerned with the differences and their reliabilities shown in the last three columns. Whereas, of the 1,670 negro children whose scores on the primary examination we are considering, only 79 were in the first grade, there are 662 white first graders in the 2,039 cases we are now using for comparison. The negro means, then, especially at the lower ages, eliminating as they

do the duller children who are in the first grade, are most probably higher than they should be. This comparison gives a slight lead (0 35) at age 7 to the group under study, which, when taken into consideration with its large probable error (±0.65), becomes entirely negligible. At all succeeding ages through 11, the Otis group are substantially ahead, regardless of the question of selection, and at age 12 the difference in favor of the negro (0.94) is smaller than its probable error (±1.30) The lead of the white children increases through year 9, beyond which age there is evidence that the problem of retardation is affecting their scores much more seriously than it is those of the negroes. The number of cases of white children begins to fall off markedly at year 10, indicating that the majority of children of these ages are further advanced in school.

The data [9] from which Otis standardized his primary examination has 240 cases of 10-year olds in the fifth grade, in comparison with his 306 cases of lower grading that are now being considered. At 11 years, at which age there are 127 of his cases in the first four grades, there are 135 in the fifth grade, and there are the same number of 12-year olds in the fifth grade in comparison with the 70 more retarded cases On the other hand, reference to data here presented for negroes (Table 4, column 2) shows that there are 328 10-year olds in the first four grades to 83 in the fifth and sixth, 215 11-year old "primaries" to 180 "advanced," and, for 12-year olds, 211 "primaries" to 246 "advanced." If these two lots of data may be taken as typical, school retardation is more prevalent among the Negroes; the average white child of a given age is more advanced in school than the colored child of the same age; and the retarded colored child is a more normal racial representative than is the retarded white.

Otis's age-grade distribution for the advanced examination [10] leads to the same conclusion. The number of cases below, coincident with, and above the fifth and sixth grade selection in this study, are as follows:

Age	Grade 4	Grades 5 and 6	Grades 7, 8, 9, 10, 11, and 12	Age	Grade 4	Grades 5 and 6	Grades 7, 8, 9, 10, 11, and 12
10	1,972	2,435	38	13	330	1,918	4,229
11	1,077	4,186	616	14	120	842	4,345
12	575	3,565	2,508		•		

The conclusion seems fair that, on the primary examination, white children 10 years old and older who have not progressed beyond the fourth grade are too inferior to be used as racial representatives, and on the advanced examination the fifth-sixth grade selection does not give fair white averages beyond year 11. With the negro group

[9] Ibid, p. 80. [10] Ibid, pp 76-77.

here studied, the age-grade distribution seems to imply that for 11-year olds the primary group is probably the more typical, but that for 12-year olds the advanced group is certainly the more "normal." The results indicate, also, that beyond the latter age the negro subjects still in the elementary schools are inferior members of the race and can not with fairness be used as a basis for comparison. On the advanced test, at 10 and 11 years, where retardation seems to affect neither race—though the negroes at these ages are probably the more accelerated, relatively—the superiority of the white child is attested by differences (23 88 $\pm$1 86, 25.00 $\pm$1 19) which, when referred to their probable errors, are seen to be very large and reliable; the difference at 11 years is somewhat larger and more reliable than that at 10

Before leaving Table 4 it might be noted that, in all cases, especially before retardation plays a prominent part, the means, when taken into consideration with their probable errors, are seen to be quite distinct and reliable, and that the group variabilities, as measured by the standard deviations of the distribution, are generally greater in the cases of the white children.

Figure 1 pictures the various relationships which have been discussed. It shows that regardless of yearly increments (through age 12) the negro falls progressively below American white norms and below their averages, unless the latter are unduly weighted with retarded cases. Actual deterioration in performance in the case of 13 and 14 year old negroes is not assumed on the basis of present evidence, and those ages are not excluded from the generalizations In like manner, when the selected American white cases give means that fall below those of preceding years (see dotted line on graph), whereas other data prove that in reality the yearly improvement curve is still advancing (see broken line), the selection that deviates from the trend shown by the more inclusive data must be discounted Figure 2 pictures the same facts in terms of relative or proportional change rather than of concrete units.

Since, in considering crude or total scores on the Otis test, it is essential to keep distinct the primary and advanced examinations, the number of cases at each age level can be increased—and so the statistical adequacy—if total scores are not used, but "percentile ranks," which are said by Otis [11] to be comparable in the two examinations. These percentile ranks, of course, presuppose a norm. The child whose score coincides with the norm for his age would have a percentile rank of 50, meaning that in a normal distribution he would excel 50 per cent of the cases and be excelled by 50 per cent. A percentile rank of 10 means that a child excels 10 per cent of children of his age and is excelled by 90 per cent.

[11] Ibid, pp. 52-53.

The appendix gives the complete age and grade distribution, by percentile ranks, of the children of this study. The same data are condensed in Table 5, which emphasizes the clinical groupings, giving the number and the per cent of cases of each age which fall within each of the major categories. It will be seen that in the "feeble-minded" and "borderline" groups the percentage of cases generally increases with age, whereas in the "normal," "superior,"

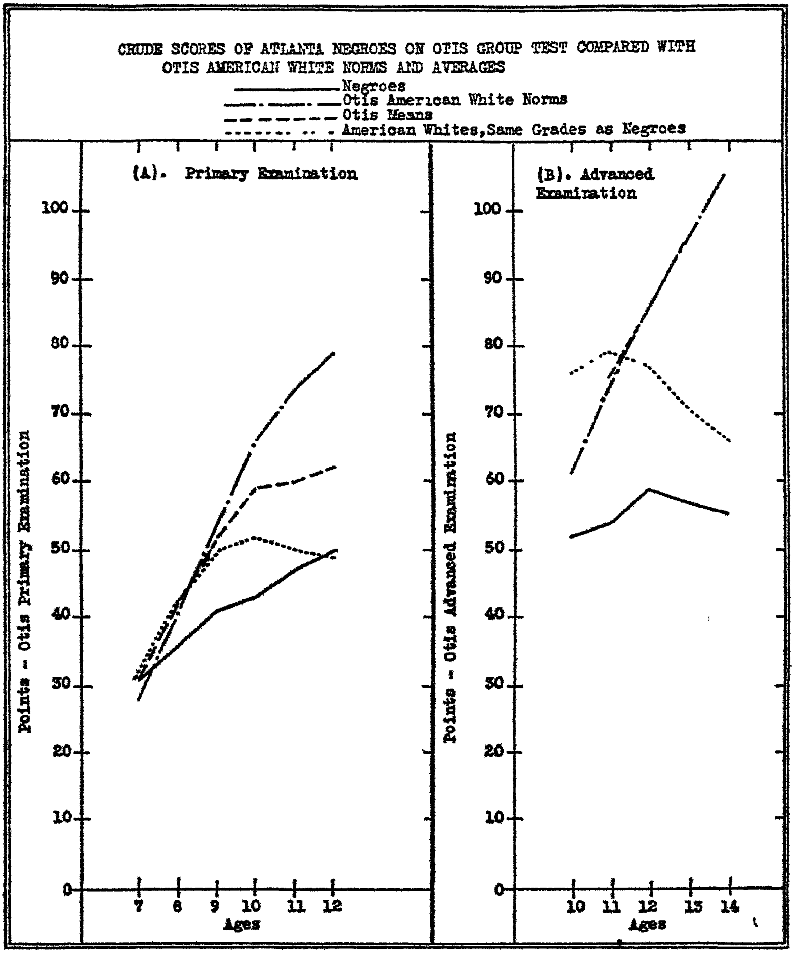

FIG 1

and "very superior" groups it decreases. The central tendencies of the age levels are seen to move constantly from the superior to the inferior extremes with increasing years.

Table 6 gives the means and variabilities of percentile ranks for the several ages. The mean is lower at each succeeding age. The seven-year mean denotes a good average performance (by American white standards); the eight and nine year scores, though increasingly

lower, come within the range of "normality"; by 10 years the mean in this group of negro children has fallen below the lower limit of "normality" into the region classified as "dull", and therein are found all the means of the higher ages.

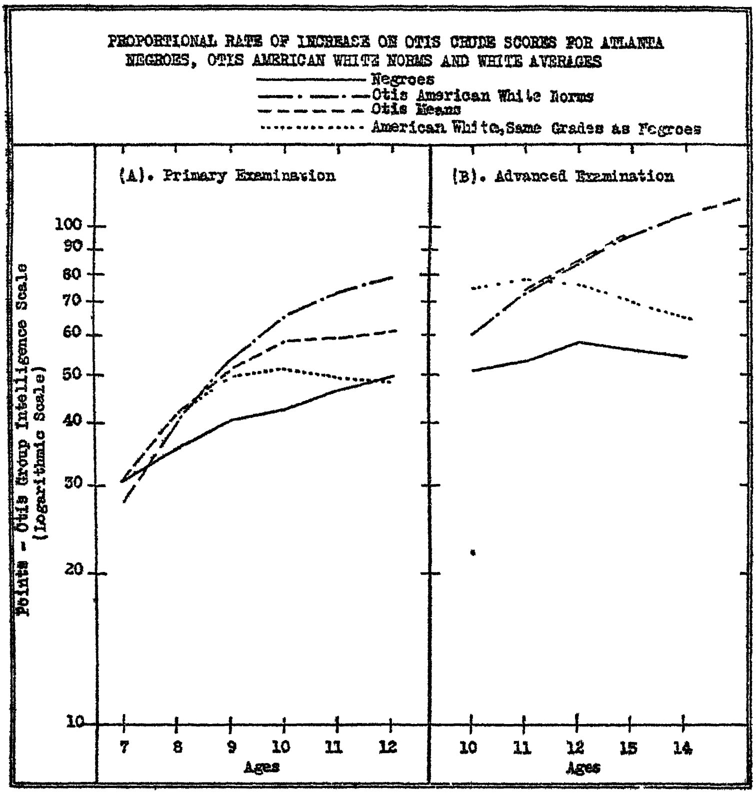

FIG 2

TABLE 5—*Percentile rank distribution on Otis tests, by age and clinical groups—Atlanta negro children*

Age	0 00-0 49, feeble minded		0 50-4 99, border line		5-19, dull		20-79, normal		80-94, superior		95-99 9, very superior		Total
	Cases	Per cent	Cases	Per cent	Cases	Per cent	Cases	Per cent	Cases	Per cent	Cases	Per cent	
6							44	74 6	13	22.0	2	3 4	59
7					22	10 2	159	74 0	30	14 0	4	1.9	215
8			10	3.0	78	22.6	225	66 8	16	7 7			337

14	201	10 06	±.73	15 38	±.52

It is interesting to note that the results here presented are not at variance with those of other investigators. In 1923-24 a survey of specially handicapped children was made in the State of Illinois, and a preliminary report [12] has been published. This distribution table [13] shows the negroes to have lower averages and lower variabilities than the whites. A further analysis of data from this survey gives the racial comparisons shown in Table A The scores from group and individual tests were all reduced to terms of intelligence quotients.

TABLE A —*Differences between I Q scores of whites and negroes—Illinois survey*

Age	Difference	Age	Difference	Age	Difference	Age	Difference
6	10 6±1 3	9	20 1±1 3	12	26 7±1 0	15	18 7±1 6
7	17 3±1 9	10	25 2±1 1	13	31 0±1 1	16, 17	15 1±2 2
8	19 6±1 9	11	29 1±1 2	14	22 0±1 4		

These children come from the first eight grades and the greater part of the negroes, as of the whites, are classed as "urbans." The difference tends to become larger with age—at least through age 13, beyond which point there is the possibility of selection and retardation again being operative. These figures, though obtained from subjects in a different part of the country and living under different social conditions, and though the data were secured from other tests administered by other examiners, obviously support the conclusions derived from the Atlanta study.

III. The Individual Examinations

The individual examinations followed the group tests in each school. As has been stated, as many as possible of those who made low scores on the Otis tests—generally those with percentile ranks of "5" or below—were given further examination. Similar individual tests were given to a number of psychologically unselected 6 and 7 year old first graders, and also to such special or problem cases as were referred by principals and teachers. There is available for study the results of 604 individual examinations, though all of the performance tests were not given to all of these children.

The Stanford revision of the Binet-Simon Scale was used as the basic test in all the individual examinations and was believed to yield the most reliable data for individual diagnosis. The Kohs Block-Design test was given to 201 children, and was then dropped from the schedule. In view of the poor work done on this test by most of the negro children, the examiner thought that sufficient material

[12] Adler, Herman M Report of the Survey of the Specially Handicapped Children in the State of Illinois. State publication, 1925.

[13] Ibid., p. 11.

had been collected to show a racial inaptitude for this type of performance and that the time could be better devoted to securing data with other psychomotor tests. Thereafter, the Lincoln Hollow Square form of board was used with most of the children, giving records, in 369 cases, of the number of problems solved within the one minute time limit, and also of the average seconds per problem. In calculating the last item the time was taken, to the nearest second, of each problem solved within the minute, each failure was given a score of 90 seconds, and the total time was divided by 8, the number of problems. Healy Construction Test A was used in 274 cases. The procedure differed somewhat from the generally prescribed one in that the work was discontinued if the problem remained unsolved at the end of three minutes, whereas the standard time limit is five minutes. This was done because decided difficulty was experienced in inducing most of the children to continue their efforts even as long as the three minutes. The great majority of those who did not succeed within a much shorter time lost interest or became discouraged. They frequently stopped and urging was necessary to get them to work until the end of the shorter interval. If the child failed, he was quietly shown how to fit in the pieces—unsupplemented by any verbal explanation—and in any case a second trial was given. If the first trial was a success, the child was asked to see whether he could do it more quickly next time. Five trials were given and in every case where the preceding one had been unsuccessful, the child was shown before being asked to try again. In computing the total time for the five trials, 180 seconds was used as the score for each failure.

Table 7 gives the intercorrelations of the test scores [14] and Table 8 gives the same correlations, with the factor of age distributed or held constant. The coefficients are naturally lowered in the second instance, since, in a group of varied ages, the mere factor of chronological age rather than that of relative intelligence for age, is responsible for the fact that many correlations are high. The child who does well in one test is likely to do well in another, *because he is older* rather than because he is proportionately more intelligent than the younger child who makes lower scorings on both.

[14] In calculating the correlations for the first trial of "Healy A" test the failures are placed at 180 seconds. Placing them at 300, the standard time limit, raises the correlation with the Otis Primary Score from −0 169 to −0 175. The correlation with the Lincoln test, average seconds per problem (0 078) becomes 0.100 if the failures are valued at 400, and −0 282 if the 108 failures are eliminated altogether. Omitting the failures from the calculation is ignoring a large and significant part of the data, and obviously gives an erroneous coefficient, since it implies that the cases used are believed to be typical of all The question of the fair placement of the failures is not so easily settled, but within the limits experimented with, the resultant difference to the correlation seems quite small. In subsequent calculations based upon these coefficients, our arbitrary placing of failure at 180 gives prediction scores more favorable to the children studied than had a higher value been used.

TABLE 7.—*Test intercorrelations—Atlanta negro children*

[1] See footnote to Table 7

Binet mental age and the two measures of the Lincoln test are seen to be the most dependent upon chronological age, and the advanced Otis test the least so. The last should not be unexpected when we consider that a large part of the Otis scores are obtained from the

older, retarded children Kohs and Lincoln tests yield the highest correlations with the Binet—probably the most dependable single measuring instrument—when the effect of age upon the relationships is eliminated. The correlation of Otis percentile rank and Binet intelligence quotient is positive and, in the light of its probable error, quite reliable; but the coefficient (0.377±0.027) does not seem as large as might have been expected in the case of two indices each of which is, in itself, a measure of brightness irrespective of age. The first trial of the Healy test, if it measures anything at all in this group of children, measures something that seems to be quite different from what is measured by all the other tests—the coefficients, age constant, ranging from −0 13 to 0 13. The total time of five trials on the Healy, however (see Table 8), has a decidedly high correspondence (−0 79) with the Otis Advanced, and a real, though not as marked, correlation with the Otis Primary (−0 25). The average seconds per problem on the Lincoln also seems to be an excellent indication of accomplishment on the Advanced Otis (−0 80). It is interesting to note the four low correlations between the Lincoln and the Healy Tests (0.01–0 08), though both are psychomotor problems of the form board type and proficiency in the two might have been expected to be closely related. On the contrary, however, facility in handling the one test seems to give us no prediction of what may be expected with the others.

If attempt is made to summarize and generalize from these correlations, there would seem to be justification in saying that the Kohs test gives a fairly good measure of intelligence as gauged by the Binet and the Otis primary tests. The Lincoln test also corresponds satisfactorily with the verbal tests—provided the relationship between the number of problems solved in the former and the score on the Otis Advanced be excepted. This does not seem contradictory when it is considered that there are only eight problems, and that these, being designed for younger children, do not give an adequate range for the older subjects of the Otis Advanced. The Healy test seems to have little in common with the other measures, if only the first trial on the construction problem is considered, but the total time of five trials does give an excellent indication of accomplishment with the Otis Advanced and a very good one with the Otis Primary. The Lincoln and the Healy tests apparently do not measure the same thing.

1. THE STANFORD BINET TEST

Due to the nature of the selection of cases for individual examination in the study, largely by inferior performance on the Otis scale, the data are not such as are capable of yielding objectively adequate measures of racial performance. There are, however, unselected

groups of 6 and 7 year children, whose showing on the Binet scale is interesting to consider. Table 9 gives the comparative scores of the two ages.

TABLE 9.—*Stanford-Binet scores of unselected 6 and 7 year old negro children*

Age	Number of cases	Mental age: Mean (years-months)	Mental age: Probable error (month)	Mental age: Standard deviation of distribution	Mental age: Probable error	Intelligence quotient: Mean	Intelligence quotient: Probable error	Intelligence quotient: Standard deviation of distribution	Intelligence quotient: Probable error
6	54	6-9.7	±0.87	9.43	±0.61	103.2	±1.04	11.32	±.73
7	51	7-0.3	±.83	8.76	±.58	94.8	±1.01	10.72	±.72
		Months		Probable error of difference		Intelligence quotient		Probable error of difference	
Differences[1]		2.6		±1.20		−8.5		±1.45	

[1] Minus sign indicates score of 7 year olds is lower than 6 year olds

In considering totality of performance, as is done in this table, it is noted that, in terms of mental age and of intelligence quotient, both 6 and 7 year groups are thoroughly "normal" by American white averages. There is the same falling off with age, relative to white standards, that was noted consistently in the study of the Otis test results The difference in intelligence quotient between the ages (-8.5 ± 1.45) is quite reliable statistically and is the more significant since it reinforces conclusions drawn from other data,[15] and gives some indication of the age at which this increasing "slowing-up" in mental development on the part of the group studied can first be observed.

The Stanford-Binet test is capable of yielding much information of a qualitative kind on the types of performances at which the subjects do their relative best and worst; but this has not been attempted in the present paper. The examiner's observations, however, while they are not offered as accurately calculated statistical findings, may not be without interest, regardless of their partly subjective nature. There was noted what may be described as lack of sensory discrimination in various fields, coexistent with inability to criticise or see discrepancies between accomplishment and the ideal or pattern. Illustrative of this, for example, are inferior work with weight discrimination (IX_2), in giving rhymes (IX_6), and in many instances of word definition, as well as in some performance tests which will be discussed in a later section. With reference to inaccurate interpretation of verbal stimuli, it is interesting to note that, even after the difference in spelling and in pronunciation between the given word and the one

[15] The writer in an unpublished M. A thesis found that with negro children, aged 8-12, from the colored public schools of Lexington, Ky., all ages made averages inferior to those of whites, on a summation of points from several individual tests of the Cornell series, but differences between race averages were similar at each successive year.

with which it was confused had been pointed out, large numbers—in fact it seemed most of the children—persisted in intepreting "copper" (vocabulary test) as "copy," "pork" as "poke," "lecture" as "electric" or "election," and "civil" as "silver." In like manner, it seemed that the great majority of children defined "charity" (XII_2) as "something to ride in" or "a hearse," and "justice" as " 'cute' ingestion" (acute indigestion). In other words, a vague similarity of sound with some better known word was sufficient to prevent them from getting an accurate auditory conception of the one in question. It also seemed that they were relatively inferior in repeating digits backward and in copying the diamond (VII_6). The tests in which they seemed most proficient were those of a practical nature, such as knowing coins (VI_5) and tying a bow (VII_4). They also gave the impression of doing well in auditory rote memory and in interpretation of pictures (XII_8—verbal imagination?). To summarize, the examiner's belief is that they do best at practical and rote performances, and poorest at those performances involving discrimination and critical accuracy.[16]

Upon qualitative race differences comparatively little work has been done Two recent articles [17] reporting experimental investigations with white and negro children, stress the need for analytical study of the individual rather than for the creation of race norms in terms of general intelligence.

2. KOHS BLOCK DESIGN TEST

In Kohs block-design test the subject is required to reproduce, with a set of colored cubes, certain color-form designs which are drawn on cards. The designs vary in size and complexity, and a point scale has been worked out which makes deductions from each maximum design value for excess time and moves. The final point score may be interpreted into "mental age." The method of procedure described by Kohs [18] was followed by the examiner in administering and scoring this test.

The impression was soon gathered that this test held special difficulties for the negroes; their score on the block designs seemed to be much inferior to their showing on the Binet test. Especially striking was what appeared to be an inability to criticize their own work, to recognize a failure as such, a tendency to offer a markedly erroneous

[16] The writer's study, previously referred to, showed, by quantitative measurement, the negroes studied to be superior to the whites in immediate memory for familiar objects, but inferior in processes involving reasoning and judgment and in mental content or fertility of ideas.

[17] Sunne, Dagny Comparison of White and Negro Children by the Terman and Yerkes Bridges Revision of the Binet Tests Peterson, Joseph: Lanier, Lyle H , and Walker, H. M. Comparison of White and Negro Children in Certain Ingenuity and Speed Tests Both articles in The Journal of Comparative Psychology, Vol V, No. 3, June, 1925.

[18] Op cit, pp. 64-77.

solution with an apparent self-assurance of its correctness. This is decidedly in keeping with the general type of performance discussed in the preceding section on the Binet tests; accurate analytical and critical work seems difficult for the negro.

The block design test was given to only 14 unselected 6-year-olds—children who were not tested because of low scores on the Otis—and to the same number of unselected 7-year-olds; but regardless of the few cases, something of interest may be gleaned from the results. The mean point scores for the 6 and the 7 year olds, respectively, were 1.4 ± 0.15 and 2.0 ± 0.26; their standard deviations were 0.8 and 1.5. Kohs [19] gives 4 points as the score corresponding to a mental age of 6 years 6 months, and 8 points as the score for 7 years 6 months. It will be remembered that on the Stanford-Binet and the Otis tests, the subjects of this study of these two ages made decidedly favorable showings. It seems, then, that regardless of good general intelligence, as measured by our most reliable tests, the 6 and 7 year old negroes give evidence of inability to handle the block designs. The 2 point score obtained by the 7 years 6 months children coincides with what Kohs considers the norm for 6 years 0 months; and while the 6 years 6 months subjects in the present study average 1.4 point, Kohs makes 1 point the norm for 5 years 7 months.

The remainder of the 201 children who were given the Kohs test were the older ones, most of whom were examined because of inferior scores in the group test; and it is obviously unfair to consider results obtained from such subjects as typical of racial performance. Such evidence as was obtained about the interrelations of the factors of age, Otis score, and Kohs points with the group studied and by means of a regression equation [20] affords *predictions* of the *most probable* Kohs score, the other two factors being held constant. That is, knowing the means and the standard deviations of each of the three factors in question, as well as their intercorrelations, what children of a given age and given score on the Otis would *most probably* average on the block designs can be computed. The ages 8, 10, and 12 have been taken, and for each age the score on the Otis primary which was found (see Table 4) to be the average for that particular age the corresponding predictions for the Kohs have been computed. The predicted block-designs scores are as follows: 8 years, 3.3 points; 10 years, 6.1 points; 12 years, 8.6 points. This means that for children of an average age of 8 years 6 months, whose work on the Otis primary test is average for this age, and who therefore are *not*

[19] Ibid, p 73

[20] T. L. Kelley's regression equation for three variables is.

$$X_1 = r_{12.3}\frac{\sigma_{1.23}}{\sigma_{2.13}}X_2 + r_{13.2}\frac{\sigma_{1.23}}{\sigma_{3.12}}X$$

the selected inferiors that the actual present subjects were, the most probable score on the Kohs test would be 3 3 points It must be emphasized that these figures can not be presented with the finality, and must not be accepted with the confidence, that more strictly empirical data (objectively obtained measures) would justify. All they tell is that, in the light of the present data, the mutual interrelations of the factors considered afford the belief that the predicted scores indicate the general trend and are the most probable averages With this word of warning about their interpretations, the results yielded by the regression equation may be considered briefly.

When these predicted scores for 8, 10, and 12 year old children are compared with Kohs's norms for each of these mid-year points, the discrepancies are somewhat startling The predictions made for these ages are, in order, 3.3, 6 1, and 8.6; Kohs's norms are 14, 30, 54.

Comment concerning the writer's findings with Chinese children on this test may be of interest [21] Sixty-three Chinese 12-year olds made an average of 65.4 points on this test This score, the mental age equivalent of 13 years 4 months, surpasses their average Binet mental age (11 years 5 months) and even their chronological age (12 years 6 months) The Chinese apparently show a special facility in handling this type of problem—one which is beyond both their Binet performance and the American average for children of their years—whereas the negroes in the group under study showed a marked disability in this line of work, their scores herein being inferior to white norms and to their own records in verbal tests. Here, apparently, is a measure of racial differences, though just what the true significance of the measure is would be more difficult to say.

It will be remembered that Kohs test bore a higher correlation with the Stanford-Binet age constant than did either of the other performance tests used with this negro group. The coefficient (0.37), while very good for the correlation of a verbal with a performance test, is not high as test intercorrelations between verbal tests generally run, and is lower than the correlation between block designs and Binet (0 49) in the case of the Chinese 12-year olds referred to, and lower than the similar correlation coefficient (0 83) obtained by Kohs in the case of 366 American white children. It must be concluded, then, that while the negro's ability to solve the block designs is slightly concommitant with general intelligence as measured by other and surer means, his block-design ability lags decidedly behind his general ability and indicates a special racial inferiority in the factors that contribute to success at this type of work.

[21] Graham, Virginia Taylor The Intelligence of Chinese Children in San Francisco Journal of Comparative Psychology, Vol VI, No 1, 1926, pp 55-56.

3. THE LINCOLN HOLLOW SQUARE TEST

This test consists of eight problems, of the form board type, which vary in difficulty. The scoring in this investigation, in terms of number of problems solved within one minute, and of average seconds per problem, has already been described.

As with the Kohs test, the objective data for unselected 6 and 7 year olds (37 and 33 cases, respectively), can be given, but they must be confined to predictions obtained from regression equations for the higher ages. Table 10 gives these figures.

TABLE 10.—*Scores on Lincoln hollow-square test—Atlanta negro children*

A. ACTUAL MEASURE

Age	Cases	Number of problems solved: Means	Number of problems solved: Standard deviation	Average number of seconds per problem: Means	Average number of seconds per problem: Standard deviation
6	37	4.5±0.13	1.2	55±1.17	11
7	33	4.9±.19	1.6	52±1.55	13

B. PREDICTIONS

1. AGE AND OTIS PRIMARY CONSTANT

8		5.3		48	
10		6.2		39	
12		7.1		31	

2. AGES AND OTIS ADVANCED CONSTANT

11		5.4		47	
12		6.0		40	

There is little or nothing with which these results may be compared. The originators of the test give data [22] from only 35 children, and nothing is known about their selection of cases. There were seven 6-year olds, and seven 7-year olds among their subjects. The median total time (and in calculating total time each incomplete problem is given a score of 60 seconds, instead of 90 as was used in computing the average seconds per problem) is 165 seconds for the 6-year group and 170 for the 7-year. This is obviously very inadequate for a comparison, but it seems to indicate that Lincoln's subjects did better than those of this study—both with respect to number of problems solved and to time of solving.

Referring again to Tables 7 and 8, it will be recalled that the Lincoln test had a fairly satisfactory correlation with verbal tests of intelligence and with age. The coefficients seem to indicate that the time

[22] Op. cit., pp 56-59.

measure is a better index than is the number of problems, though the latter seems satisfactory with younger children.

With reference to the predicted scores, holding constant the Otis primary gives results that are more favorable to the negro than does distributing the Otis advanced, and since the "primary" group is less weighted with retarded cases, it is probably no more than fair to accept these better scores as being the more nearly correct.

On the Lincoln test, the present subjects seemed to do better at each successive age, both with respect to the number of problems solved and to the time of solving them. The test correlates to some extent with verbal intelligence tests, but not with the Healy construction A There are available no comparable data on which to base an estimate of how well or how poorly the negro children do on the test, with reference to the accomplishment of children of any other race.

4 HEALY CONSTRUCTION A

As has been pointed out previously, the time required for the first solution of the Healy A seems to be completely unrelated to any of the other tests or measures, so far as this negro group is concerned. The total time of the five trials, however, does bear some relationship to accomplishment in the verbal tests, and a marked one in the case of the Otis advanced Unfortunately, all the comparable data available are in terms of time on the first trial, which, it is felt, is a psychologically unknown measure, perhaps influenced largely by chance. Children have often been seen to solve the puzzle comparatively quickly the first time, only to fail or take an inordinately long time on succeeding trials. The total time for five trials seems to be a more significant index.

As Pintner and Paterson [23] point out, there has been some disagreement in the norms offered by several investigators. Their own are probably the best basis of comparison, since, aside from being derived from a comparatively large number of cases (1,005), they are the ones that are most generally accepted. Despite great variability in individual performances at all ages, their medians [24] show a steady decrease with age As might be expected with data selected as in the case in this study, the actual medians of the group under study are most erratic, so again resort is had to predicted averages as the safest indication of performance. Table 11 gives the best that is afforded in the way of racial comparisons on this test.

---

[23] Op cit, pp 44-53, 122-126

[24] Ibid, p. 123

TABLE 11.—*Predicted scores of Atlanta negro children, compared with white norms on Healy construction A test*

NEGROES—AGE AND OTIS SCORE CONSTANT—PREDICTION

	Primary test			Advanced test	
Age	8	10	12	11	12
Time First trial	129	120	112	128	124
Total time	263	229	200	267	228

WHITE NORMS—MEDIANS—PINTNER AND PATERSON

Time First trial	117	70	46		

Again preference is given to the predictions based on the Primary rather than on the Advanced examination; they are more favorable to the group With reference to time on the first trial, these figures indicate the white to be more successful in the solution of this problem. The scores of the two races are closer together at the lower ages

Little can be said about the significance of this test Just what factors are involved in this type of problem solving it would be difficult to say; "appreciation of form-space relationships" and "psycho-motor ability," are somewhat vague phrases, and it would be reverting to an outgrown "faculty psychology" if attempt were made to extract herefrom the indicators of more specific "abilities." Nor is there objective criteria to indicate the practical or industrial aptitudes of which the test is a measure. When the five trials are used, and the problem becomes a learning test, still other psychological elements are introduced; but further and fuller analysis is needed to determine the value of the form board as a prediction of social or economic adequacy, either general or specific.

IV. Summary and Conclusions

In this study no pretense is made of having adequately analyzed negro intelligence from the qualitative standpoint. Nor is it believed that any of these tests are magic or infallible indicators of the thing called general intelligence. A clinician is only too well aware of the distorting influence of the conditions known as "attitudes" and "interests"; and intelligence, in itself, remains too much of an unknown quantity to be dogmatized about. This study has been based upon results obtained from the use of a group test (Otis) that is generally accepted as a good measure of general ability, of an individual test (Stanford Binet) that is conceded to be the most accurate and dependable measuring rod, and upon several performance tests (Kohs block design, Lincoln hollow square, and Healy

construction A), about the specific indications of which less can be said with definiteness

The ideal procedure in such a racial investigation would seem to be, of course, to compare groups of white and negro children that had been subjected to the same social and educational influences, that is, to measure test performance, experience being held constant Such a method is, however, practically impossible Comparisons have, therefore, been based upon norms secured from large numbers of white children in various parts of the country, and an attempt has been made to eliminate such factors as seemed, *a priori*, to put the negro at a disadvantage Moreover, considering the probable discrepancy in status between the white and the negro children compared in this paper, the comment may be pertinent as to whether, had their environments been the same, the selected groups would not have been as representative of the respective races as are the ones used.

Taking the results "behavioristically," without any over-interpretations, as objective data accumulated through the scientific method of "controlled stimulus and measured response," the comparative records of the races are significant. The results found in the present study may be summarized briefly as follows:

1 On various mental tests the negro children, except at early ages, made averages that are lower than the averages of white children.

2. The discrepancy in test scores between the races increases with age, after the sixth year, and becomes quite marked by the eleventh year.

3. Variability of performance within each of the races was found, as many investigators state, to be greater than the difference between the two. The differences between the averages are reliable, however, and are constant in direction

4 In most instances greater variability of performance is shown among the whites than among the colored This increases the probability of extreme cases in the former race; and since their means are generally higher, it increases the probability of superior scores. The negro group, on the other hand, tends to hang a little closer around their lower average

5 On tests of special performance—nonverbal tests and specific parts of verbal scales—the negro children seem to do better at rote and practical tasks than at those that involve behavior which may roughly be described as discriminating, analytical and critical.

6. There seems to be little, if any, real disagreement between the results and conclusions from other related studies and those from the present study, though no attempt has here been made to

review adequately or to analyze the complete literature that is available on this subject.

No attempt is made to state the ultimate significance of these test results. Probably no one is in a position adequately to define and analyze intelligence, and the real value of many of the measures thereof is still a debatable question. The only justifiable claim of mental testing is the pragmatic one of furnishing a reliable prediction of general social and economic efficiency. The science rests upon an empirical foundation; and correctly standardized tests, though they may not differentiate and analyze endo-psychic factors, have been found to provide a basis for predictions of social and economic adequacy that have undeniable reliability.

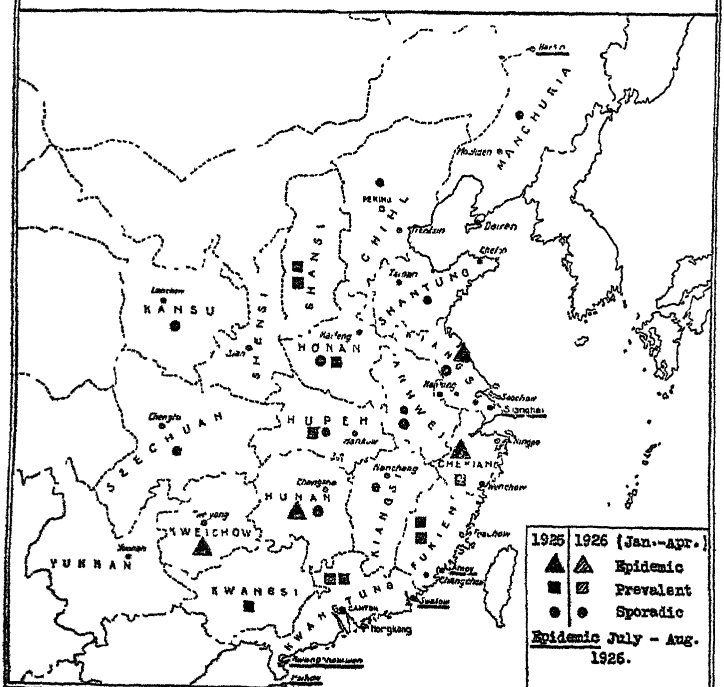
CURRENT WORLD PREVALENCE OF DISEASE

REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED SEPTEMBER 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT [1]

Additional information concerning the cholera outbreaks in China and other parts of the Far East during the spring and summer months is made available in the September Epidemiological Report, published at Geneva by the health section of the League of Nations' secretariat. While the epidemic at Shanghai, referred to in last month's report, declined during August (see table below), outbreaks were reported in Amoy and in Harbin, Manchuria, about the middle of

CHOLERA IN CHINA IN 1925 AND 1926



August; also a few cases occurred in Port Arthur and Dairen. A number of deaths from cholera were reported at Swatow in July, and rather serious outbreaks occurred at Hoihow on the island of Hainan, where 386 cases were reported in four weeks in May and 365 cases in four weeks in July. At Kwang-Chow-Wan the number of new cholera cases continued to increase during August, and 483 cases were reported as against 354 in July. In general the cholera situation in China gave cause for some anxiety at the beginning of the month of September.

While current figures for China as a whole are unobtainable, of course, the information gathered by the National Epidemic Prevention Bureau at Pekin from hospitals and practitioners of western medicine gives a good indication of the epidemic situation in the various Provinces This information was available only up to April, but at that time cholera was said to be of frequent occurrence in the two southern coast Provinces of Kwang-tung and Fukien, but not to exist elsewhere Notes from this source seem to indicate that, during the 12 months from May, 1925, to April, 1926, no Province of China was entirely free from cholera. The southern and central coast Provinces and the two inland Provinces of Kweichow and Hunan were most affected, while cases seem to have been rare in the western Provinces On the accompanying map of China some indication of the prevalence of the disease in the various Provinces in 1925 and in the first four months of 1926 is given, and the towns where outbreaks were reported in the past summer have been underlined

In southeastern Asia the cholera situation improved during the summer. In Siam 674 cases were reported in the whole country during the four weeks ended August 14, compared with 1,413 during the previous four weeks. In French Indo-China, where 722 cases were reported in August as compared with 1,768 in July, the situation showed marked improvement, and the principal ports were reported free from cholera.

The cholera deaths reported in India in the two weeks ending July 31 numbered 2,499, compared with 4,908 in the corresponding period of 1925 Western and northwestern India were practically free from cholera, and Bihar and Orissa and Madras Presidency showed the highest incidence. No unusual prevalence occurred in the Indian ports.

TABLE I.—*Cholera cases reported in the principal maritime towns of the Far East from August 1 to September 11, 1926*

Towns	Number reported in week ending—					
	August—			September—		
	7	14	21	28	4	11
Negapatam (deaths)	3	5	5	0	0	1
Madras (deaths)	1	0	0	0	1	0
Calcutta (deaths)	11	5	9	10	13	18
Rangoon (deaths)	1	----	0	1	0	0
Bankok (cases)	8	2	0	2	3	7
Saigon and Cholan (cases)	1	0	0	0	0	0
Amoy (cases)	0	2	11	16	38	53
Shanghai (cases)	333	171	141	100	122	57
Port Arthur (cases)	0	0	0	2	0	0
Dairen (cases)	0	0	0	1	2	2
Yokohama (cases)	0	0	0	1	0	0
Harbin (cases)	0	36	95	66	46	27

Plague.—"Returns for August show a relative quiescence of plague in its principal centers, as is usual at this season," says the report. In the Mediterranean countries the only cases reported during the month were 4 at Constantinople, 2 in Greece, 2 in Algeria, 1 in Tunisia, and 1 in Egypt, at Alexandria

In the Union of South Africa only 2 cases of plague were reported in August as against 11 in July. No cases have been reported from Tanganyika Territory since last November, and in Mauritius the one case reported during July was the first since last December In Madagascar plague reached its lowest incidence during July with 16 cases, and an increase occurred in the first half of August when 30 cases were reported.

In Senegal and Uganda the incidence of plague has been higher than in the previous year. During May and June 321 cases were reported in Senegal, compared with 95 cases the corresponding period of 1925, which was, however, an unusually low year. In Uganda the number of cases was declining somewhat in July, but between January 1 and August 7, 1,128 cases had been reported compared with 470 cases during the corresponding period of the previous year.

Plague cases reported in India during the two weeks ending July 31 numbered 562 as against 490 in the corresponding two weeks last year; 179 cases were reported in Bombay Presidency, 91 in Madras Presidency, and 226 in Mysore.

In Java there were 139 deaths from plague in the four weeks ending July 17 as against 461 and 518 deaths, respectively, in the corresponding periods of 1925 and 1924

In Siam only 1 case of plague was reported in July, and in French Indo-China there were 22 cases reported in July and 12 in August

Japan reported 9 cases of plague in July, all in the Province of Kanagawa and 6 of them at Yokohama. There was no case in August.

Yellow fever.—The following cases of yellow fever were reported:

Africa
- Gold Coast—June, 2 cases, 1 death.
- Nigeria—June, 1 case, 1 death.

South America
- Brazil—
  - Parahibo—April, 40 cases, 8 deaths.
  - Rio Grande del Norte—April, 50 cases, no deaths.

Smallpox.—The outbreak of smallpox which began early in the year in Japan evidently had come to an end in August, for only nine cases were reported in the first two weeks of the month. The total cases reported in the first seven months of the year numbered 1,219.

Smallpox was reported to be prevalent in all parts of China in March and April, and epidemics were indicated in the Provinces of

Chihli, Honan, Chekiang, Fukien, and Kweichow. "As elsewhere in the Northern Hemisphere," says the Report, "smallpox seems to be most prevalent in April, least in September"

The smallpox cases in European Russia, excluding the Ukraine, in April totaled 373 as against 1,060 in April, 1925, and 2,480 in April, 1924. Only 22 cases were reported in the Ukraine in April and 27 in May

A marked seasonal decrease in smallpox occurred in England during July and August; 291 cases were reported during the four weeks ended August 14, compared with 585 during the previous four weeks

A severe smallpox epidemic of virulent type was reported in July at Rio de Janeiro.

In the United States there were 592 cases reported by 38 States during the first fortnight of August, compared with 367 in the corresponding period of 1925

Dysentery.—The prevalence of dysentery reported by European countries during August is summarized in the following paragraph taken from the Report:

Dysentery has, on the whole, been less prevalent in Central Europe during the past summer than in 1925 There were 616 cases in Germany during the four weeks ended August 28 as against 1,182 cases during the corresponding period of the previous year Fifty-two cases were reported in July in Czecho-Slovakia and 145 cases in Hungary as compared with 127 and 211 cases, respectively, during the corresponding month of 1925 In the Kingdom of the Serbs, Croats, and Slovenes there were 236 cases in August, 1926, as against 301 cases in August, 1925 The disease was, on the contrary, somewhat more prevalent in Poland than in 1925: 1,437 cases were reported during the four weeks ending August 28 as against 1,049 cases during the corresponding period of the previous year. The returns for May for the Ukraine showed a slightly higher incidence than in 1925.

Enteric fever.—Although seasonal increases in enteric fever were evident for most European countries, the July incidence was lower than during the corresponding month of the previous two or three years in nearly all countries. "It would be premature, however, to draw any final conclusions, as yet, on the typhoid fever situation," says the Report, "since the maximum incidence of the disease rarely comes before September, frequently in October, and, at times, as late as November."

Acute poliomyelitis—Both Germany and England reported more cases of poliomyelitis during July and the first two weeks of August than in the corresponding season of 1925, while the other countries

reporting on this disease showed a lower incidence than last year. A comparison of cases in the two years is given in the following table:

TABLE II.—*Cases of poliomyelitis reported in various countries, 1925 and 1926*

4-week period ending—	Germany		England and Wales		Italy		New Zealand		Month	Sweden		Denmark		France	
	1925	1926	1925	1926	1925	1926	1925	1926		1925	1926	1925	1926	1925	1926

Scarlet fever.—The number of cases of scarlet fever in Poland has been increasing steadily since June, and in the week ending September 4, 1,138 cases were reported, more than twice the number in the corresponding week of 1925. In Germany an increase began in August, and at the end of the month the number of cases was greater than in any of the four preceding years. The weekly cases reported by these two countries are shown in the table below. No corresponding increase was noted in the reports from other European countries.

TABLE III.—*Scarlet fever cases reported in Germany and in Poland from July 11 to September 4 of 1925 and 1926*

WHAT PRICE SMALLPOX [1]

By CHARLES V. CHAPIN, M. D., Superintendent of Health, Providence, R. I., President American Public Health Association

During the last 15 years there have been over 700,000 reported cases of smallpox in the United States. Last year, 1925, there were 39,639 cases. These 39,000 cases were more than occurred in any country furnishing statistics, except India. Even Soviet Russia,

[1] Quoted from the Weekly Bulletin of the Bureau of Public Health of New Mexico, dated Nov. 16, 1926.

with a larger population, had only half as many cases. The 8,000 deaths in Mexico suggest that the cases in that country were probably proportionally more numerous than in the United States, but actual statistics are lacking. What becomes of our boasted superiority in public health when we are more widely infected with the most loathsome of the contagious diseases than is any other country, but Mexico, and when we have to admit our inferiority to the Soviet Republic. This state of things is no chance event of one year. For 15 years and longer we have had more smallpox than any country in western Europe; indeed, generally more than the whole of western Europe. In 1921 we had reported over 100,000 cases of this disease

Some people are saying, "Suppose we do have a lot of smallpox; what of it? It is a very mild type of the disease It never kills anybody I had rather have it than vaccination. With modern sanitation and our cleanly habits the old loathsome smallpox has become extinct"

Has the reader ever seen a case of "mild smallpox"? If he has, certainly if "*she*" has, neither would ever prefer it to vaccination. A year ago there was an outbreak of some 50 cases of mild smallpox in the vicinity of Providence Out of the kindliness of our hearts we took four of the patients into our city hospital. They all had backache, headache, and some fever for a few days They then felt better and could sit up. The bodies, and especially the faces, of all were covered with pustules They were almost thick enough to run together. We counted nearly 2,000 on one man. In about three weeks they had turned into brown crusts and had dried up and fallen, leaving brownish spots to last for half a year. There were no deaths, so this was classed as an outbreak of the mild type I prefer a successful vaccination.

It is all nonsense about the old-fashioned severe type of smallpox being extinct. It still exists in various parts of the world, in India, in China, in Mexico, in Russia, and in other places. It has in recent years invaded the United States, from Japan, from Europe, from Africa, and most frequently of all from Mexico. In 1923 Detroit was experiencing an outbreak of mild smallpox. Nobody died. The health department did valiant work but received scant support. People would not be vaccinated The disease dragged on. Then, in January, 1924, a case of virulent smallpox came from Canada. People began to die. They lived sometimes only two or three days. The public became alarmed. They began to back up Doctor Vaughan, the health officer. He vaccinated over 500,000 in a month. The disease was stamped out, but not until 163 persons had been placed in their graves. Virulent smallpox from the same source was carried to Minnesota. In Minneapolis it caused 1,298 cases with 63 deaths. Doctor Chesley traced it to 147 localities, and the average

fatality was 25 per cent. In Washington, D. C., in 1925 there were 59 cases with 20 deaths. During the first quarter of this year there were, in Los Angeles, 812 cases with 136 deaths. Virulent smallpox is still with us. It is as cruel a disease as in the olden times. When there is no smallpox people say, "Why should we worry? Why should we be vaccinated?" That is what the 136 Los Angeles victims said last year. Now it is too late.

How many people are saying the same thing this year? What price will they pay? Intelligence and vaccination, or indifference and smallpox? Every physician and every board of health is ready to vaccinate you now, before it is too late. Have you consulted them as yet? If not, do it now.

Opinion of Attorney General of Tennessee Regarding Authority of Municipal Health Officers Outside of Corporate Limits

Sections 3101 (being section 7 of chapter 98, Laws of 1877) and 3102 (being chapter 28 of the Laws of 1877) of Thompson's Shannon's Code of Tennessee, 1918, read as follows:

SEC. 3101. Every municipality throughout the State having 5,000 inhabitants and over shall organize a properly constituted board of health, which, in addition to their duties as such local boards, shall also make monthly, quarterly, semi-annual, and annual reports to and in accordance with such form and instructions as said State board of health may prescribe, and also shall make special reports whenever required.

SEC 3102. The boards of health established in the various cities and towns of the State shall have the same jurisdiction and authority to do all acts in the territory extending one mile from the corporation line, in any direction, that they have within the corporation, but the jurisdiction herein conferred shall not extend beyond the limits of the county in which any city or town is situated and if two cities lie nearer than two miles of each, the jurisdiction in distance shall be divided between them.

In response to a request by the State commissioner of public health relative to the authority of city and town health officers beyond the limits of their respective municipalities, the attorney general of Tennessee rendered the following opinion:

(1) The provision of section 7, chapter 98, acts of 1877, is valid, and boards of health established in cities and incorporated towns may exercise their authority in the territory extending a mile from the corporate limits. Ordinarily this must be preceded by ordinance establishing a board of health and providing for the territory specified, unless the municipality is operating under some special charter or act of the legislature.

(2) The law provides that there shall be no conflict in authority between city and county health officers. They must act in conjunction and harmoniously in the territory over which each has jurisdiction.

PUBLIC HEALTH ENGINEERING ABSTRACTS

B. coli as Index of Faecal Pollution of Water Supplies. D. A. Bardsley. *J. of Hyg* 1926, vol 25, pp 11–25 (52 refs.). (Abstracted by W. W. C. Topley.) From *Bulletin of Hygiene*, vol. 1, No. 9, September, 1926, pp. 735–736.

This paper contains a careful and adequate review of the criteria which have, from time to time, been advocated for the identification of *B coli*, as a bacterial group, the presence of which in a sample of water affords evidence of excretal contamination. Particular attention is paid to the methyl-red and Voges-Proskauer tests as differentiating between *B coli* of faecal origin and *B. aerogenes*, the normal habitat of which is usually regarded as being grasses, grain, and fertile soil. A useful summary is given in tabular form of the evidence on which this view is based The author then records the results obtained in the examination of 525 samples of water, in which these tests were applied in addition to those usually included in a bacterial analysis. Of these samples 262 contained a coliform bacillus which fermented lactose with the production of acid and gas, failed to liquefy gelatine, and produced a clot in milk. In the case of 15 of these samples, however, all the coliform bacilli submitted to confirmatory tests gave a negative methyl-red reaction and a positive Voges-Proskauer reaction, and should therefore be classed as *B. aerogenes*. It would thus appear that in 5.7 per cent of the cases, in which *B. coli* would have been reported as present by the ordinary tests, the organism actually isolated should not have been regarded as affording evidence of excretal contamination.

(There seems reason for believing that a more adequate differentiation of those bacilli which the sanitary bacteriologist groups together as *B. coli* is a far more serious problem in the Tropics than it is in this country. See report by Pawan, *Bulletin of Hygiene*, v. 1, p. 26.)

Small Sewage Tanks. E. F. Longley, Commonwealth of Australia. Dept. Health Service Pub. (Div. San. Eng.), No. 1, 22 pp. (n. d.) Melbourne (Abstracted by W W. Jameson.) From *Bulletin of Hygiene*, vol. 1, No. 2, February, 1926, pp. 155–156.

This report is really an analysis of the records of 38 small sewage tank installations in Australia. Such installations, while of value for residences and institutions, are not a satisfactory substitute for water-carried sewage systems for communities. Their efficiency may be judged by their freedom from nuisance and objectionable odors and by a long-continued operation without clogging by solids There is insufficient information available regarding the chemical and bacteriological results obtained.

19527°—26——3

The majority of the tanks under review contained two or more chambers, but no advantage appears to be gained by dividing tanks into compartments. Such tanks, usually rectangular in shape, should be capable of holding about 24 hours' normal flow or 20 to 100 gallons per head of the population dealt with. Shallow tanks appear to work as satisfactorily as deep tanks. All tanks and drains require periodical cleaning, although one tank is noted as having been in continuous operation for 5 years, 2 for 4 years and 2 for 3 years. In 11 cases where results were not held to be satisfactory, complaints were made either of bad odors or of clogging by solids. Clogging is due usually either to faulty construction or to lack of skilled supervision.

If the disposal of the tank liquor is safe and thorough, sullage waters may with advantage be put through the tanks along with domestic sewage. In any event grease, disinfectants, very hot water, and storm water should be excluded.

In 15 installations oxidizing filters, commonly built of stone, were used for the treatment of tank liquors. These filters may cause nuisance from bad smells and from clogging by solids. They should be ample in capacity, and distribution of the tank liquors must be uniform. Grease is hostile to their good working.

The disposal of the final effluent should be a matter of some concern. If a relatively large volume of water or a highly porous soil is available, no trouble may result, but heavy impervious land is unsuitable for the disposal of these liquids. Care should be taken to avoid the ponding up of putrescible effluents in surface drains. It is not safe to assume that such effluents are pure and innocuous, and where they can not be disposed of without risk of contact with human beings they must be regarded as possible sources of infection.

DEATHS DURING WEEK ENDED NOVEMBER 20, 1926

Summary of information received by telegraph from industrial insurance companies for week ended November 20, 1926, and corresponding week of 1925 (From the Weekly Health Index, November 24, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Nov 20, 1926	Corresponding week, 1925
Policies in force	66, 011, 115	62, 149, 737
Number of death claims	12, 939	11, 965
Death claims per 1,000 policies in force, annual rate	10. 2	10. 0

Deaths from all causes in certain large cities of the United States during the week ended November 20, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925. (From the weekly Health Index, November 24, 1926, issued by the Bureau of the Census, Department of Commerce)

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended November 13, 1926, 40 States reported 2,568 cases of diphtheria For the week ended November 14, 1925, the same States reported 2,180 cases of this disease One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,300,000, reported 1,328 cases of diphtheria for the week ended November 13, 1926 Last year for the corresponding week they reported 965 cases. The estimated expectancy for these cities was 1,380 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-nine States reported 3,613 cases of measles for the week ended November 13, 1926, and 2,440 cases of this disease for the week ended November 14, 1925. One hundred cities reported 615 cases of measles for the week this year, and 969 cases last year

Poliomyelitis.—The health officers of 40 States reported 52 cases of poliomyelitis for the week ended November 13, 1926. The same States reported 78 cases for the week ended November. 14, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Forty States—this year, 3,592 cases; last year, 2,832 cases; 100 cities—this year, 1,208 cases; last year, 1,044 cases; estimated expectancy, 919 cases.

Smallpox.—For the week ended November 13, 1926, 40 States reported 377 cases of smallpox. Last year for the corresponding week they reported 293 cases. One hundred cities reported smallpox for the week as follows: 1926, 32 cases; 1925, 46 cases; estimated expectancy, 38 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Six hundred and forty-seven cases of typhoid fever were reported for the week ended November 13, 1926, by 40 States. For the corresponding week of 1925 the same States reported 675 cases of this disease. One hundred cities reported 120 cases of typhoid fever for the week this year and 65 cases for the corresponding week last year. The estimated expectancy for these cities was 104 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 95 cities with a population of more than 29,730,000, as follows: 1926, 682 deaths; 1925, 803 deaths.

City reports for week ended November 13, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded. and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Dengue, 1 case at Charleston, S C

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended November 13, 1926, compared with those for a like period ended November 14, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, October 10 to November 13, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week

ASIA

Arabia.—Aden, Jeddah, Kamaran Perim

Iraq.—Basrah

Persia.—Mohammerah, Bender Abbas, Bushire

British India.—Madras, Karachi Chittagong, Cochin, Vizagapatam, Negapatam, Tuticorin

Federated Malay States.—Port Swettenham

Straits Settlements.—Penang

Dutch East Indies.—Samarang, Batavia, Sabang, Makassar, Banjermasin, Palembang, Menado, Pontianak, Belawan-Deli, Padang, Samarinda, Tarakan.

Sarawak.—Kuching

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao

Portuguese Timor.—Dilly.

French Indo-China.—Haiphong.

China.—Hongkong.

Formosa.—Keelung.

Japan.—Yokohama, Osaka, Nagasaki, Kobe, Niigata, Tsuruga, Hakodate, Shimonoseki, Moji.

Korea.—Chemulpo, Fusan.

Manchuria.—Mukden, Changchun, Harbin, Antung.

Kwantung.—Port Arthur, Dairen.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.

New Guinea.—Port Moresby

New Britain Mandated Territory.—Rabaul

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin

New Caledonia.—Noumea.

Fiji.—Suva

Hawaii.—Honolulu

Society Islands.—Papeete.

AFRICA

Egypt.—Port Said, Suez, Alexandria.

Anglo-Egyptian Sudan.—Port Sudan, Suakin.

Eritrea.—Massaua.

French Somaliland.—Jibuti

British Somaliland.—Berbera.

Italian Somaliland.—Mogadiscio.

Kenya.—Mombasa

Zanzibar.—Zanzibar.

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria

Madagascar.—Majunga.

Portuguese East Africa.—Mozambique, Beira, Lourenco Marques

Union of South Africa.—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indies.—Balikpapan.

Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.

CANADA

Communicable diseases—Week ended November 6, 1926—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended November 6, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	5							5
Lethargic encephalitis				2	2			4
Poliomyelitis				2				2
Smallpox		1		10	5	10	11	37
Typhoid fever	6	3	9	17	1	10	1	47

ECUADOR

Plague—Guayaquil—October 1-15, 1926.—During the 15-day period ended October 15, 1926, one case of plague was reported at Guayaquil, Ecuador.

Plague-infected rats—During the same period of 7,730 rats taken, 6 rats were found plague-infected.

GREECE

Plague—Patras—October 27-29, 1926.—Plague has been reported at Patras, Greece, as follows: October 27, 1926, one case; October 29, one death.

LATVIA

Communicable diseases—August, 1926.—During the month of August, 1926, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Anthrax	2	Paratyphoid fever	3
Cerebrospinal meningitis	3	Puerperal fever	3
Diphtheria	35	Rabies	1
Dysentery	76	Scarlet fever	147
Erysipelas	24	Tetanus	2
Lethargic encephalitis	2	Trachoma	21
Malaria	1	Typhoid fever	135
Measles	10	Typhus fever	2
Mumps	3	Whooping cough	51

MADAGASCAR

Plague—September 1-15, 1926.—During the period September 1 to 15, 1926, 87 cases of plague with 78 deaths were reported in the Island of Madagascar. The occurrence was distributed by provinces as follows: *Itasy*—Cases, 6; deaths, 6. *Majunga*—Cases, 42; deaths, 33. *Moramanga*—Cases, 8; deaths, 8. *Tamatave*—Cases, 2; deaths, 2. *Tananarive*—Cases, 29; deaths, 29. The distribution according

to type was: Bubonic, 58; pneumonic, 17; septicemic, 12 cases. The urban occurrence reported was, in Tananarive town (interior), 4 cases; 4 deaths. Pneumonic, 3; septicemic, 1.

MEXICO

Smallpox erroneously reported at Tampico—June 1-10, 1926.—Later information shows that the report of two deaths from smallpox at Tampico, Mexico, for the period June 1-10, 1926, published in the Public Health Reports, July 2, 1926, page 1402, and in subsequent issues, was erroneous.

VIRGIN ISLANDS

Communicable diseases—October, 1926.—Communicable diseases were reported in the Virgin Islands of the United States during the month of October, 1926, as follows:

Island and disease	Cases	Remarks
St Thomas and St John		
Chancroid	2	1 imported.
Gonorrhea	9	1 imported
Malaria	1	Imported. Malignant subtertian.
Schistosomiasis	1	Imported. Mansoni
Syphilis	10	Primary, 1, secondary, 7.
Trachoma	1	
Tuberculosis	1	Chronic pulmonary
Typhoid fever	1	Imported
Uncinariasis	3	Necator americanus 1 imported.
St. Croix		
Dysentery	1	Entamebic.
Filariasis	10	Bancrofti
Gonorrhea	1	
Pellagra	5	
Tuberculosis	2	Chronic pulmonary

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

The reports contained in the following tables must not be considered as complete or final as regards either the lists of countries included or the figures for the particular countries for which reports are given

Reports Received During Week Ended December 3, 1926 [1]

CHOLERA

Place	Date	Cases	Deaths	Remarks
China

TREASURY DEPARTMENT

PUBLIC HEALTH REPORTS

ISSUED WEEKLY

BY THE UNITED STATES PUBLIC HEALTH SERVICE

VOLUME 41 :: :: NUMBER 50

DECEMBER 10 - 1926

SPECIAL ARTICLES

WASHINGTON
GOVERNMENT PRINTING OFFICE
1926

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

CONTENTS

PUBLIC HEALTH REPORTS

VOL. 41 DECEMBER 10, 1926 NO. 50

THE WORK OF THE UNITED STATES PUBLIC HEALTH SERVICE

The United States Daily, published in Washington, and presenting the official activities of our National Government, started on October 25, 1926, a series of articles, each one a brief sketch of the work of a bureau or office of the Government The Public Health Service was selected as the first Government bureau to be described. The eight service articles appeared as copyrighted material in the issues of October 25 to 30, and November 1 and 2, 1926. Each article was prepared by a staff writer of the United States Daily after an interview with the Surgeon General and the Assistant Surgeons General in charge of each of the seven divisions of the bureau. The Public Health Service is reprinting these eight articles with the permission of the United States Daily, for the information of health officers and sanitarians.

UNITED STATES PUBLIC HEALTH SERVICE

Personal well-being is so obviously an individual and personal characteristic that it is frequently a little difficult to convince a citizen living on the Pacific coast that his health is affected by the activities of an agency of the Federal Government 3,000 miles away. In fact, save in times of epidemic, the average citizen is likely to take little interest in the activities of his local health officials, to say nothing of those of the State or Nation. When there is an outbreak of some contagious disease in his community, he becomes intensely interested in methods of preventing the spread of the contagion. But when the outbreak has abated this interest wanes, and that is why there is another outbreak at some later date.

"In time of peace, prepare for war," was the advice of one whom the world generally concedes to have been wise. And it is advice which can be adapted profitably to the work of those charged with the protection of that vital but rather nebulous thing called public health. Preparation for war in the political and military sense does not mean merely storing up supplies of arms and munitions such as were used in the last war. If it did, modern nations would be using clubs instead of tanks, and bows and arrows instead of poison gas and heavy artillery. Preparation for war means constant efforts to improve weapons and constant diligence to prevent the outbreak of

hostilities; or, if the latter is impossible, then an effort to so localize the outbreaks as to reduce the enemy's potentialities for damage to a minimum.

It is the duty of public health authorities not only to fight epidemics and diseases while they are actually present but to devise means of preventing epidemics and diseases. This is the reasoning back of the elaborate and far-flung system of disease prevention and control which, in the aggregate, is the United States Public Health Service.

In carrying out its duties the Public Health Service employs more than 8,000 men and women, and expends appropriations aggregating more than ten and a half millions of dollars annually.

The organization now known as the Bureau of the Public Health Service had its origin in the Marine Hospital Service, which was established by an act of Congress approved July 16, 1798 This act authorized the President to nominate and appoint medical officers to furnish care to sick and disabled seamen at such ports and other places in the United States as presented needs for services of this nature. It was provided that this care might be given either in hospitals maintained by the United States or in civilian institutions with which contracts might be negotiated.

A tax of 20 cents per month to be collected by collectors of customs from all seamen employed on American vessels engaged in foreign and coastwise trade was the method prescribed by the early legislators for the financing of their first step in safeguarding the public health. It is for this reason that the Public Health Service is a part of the Treasury Department to-day.

The first marine hospital built under the authority of the act of 1798 was at Norfolk, Va., in 1800 In 1802 a hospital was built at Boston, and others followed both along the Atlantic seaboard and along the Mississippi and Ohio Rivers and the Great Lakes.

Necessarily, in caring for sick and disabled seamen in American ports, the medical officers appointed to serve in these early marine hospitals became familiar with the diseases brought into the country from abroad. It frequently happened that these medical officers were the first physicians to diagnose such diseases as cholera, yellow fever, and smallpox, which threatened the welfare of ports of entry. This was particularly true in southern ports, then exposed to frequent dangers from yellow fever.

During epidemics in the early days the Marine Hospital Service frequently received presidential authorization to aid local health authorities in relief and control measures. The marine hospitals and some of the medical personnel as well were used by both the North and South during the Civil War for the care of the military forces.

Gradually, Congress began to extend the functions of the Marine Hospital Service, and to make of that organization a Federal health service. In 1878 the service was given authority to impose quarantine to prevent the entry of disease into the United States from abroad. It was not until 1890 that authority was given to impose quarantines to prevent interstate spread of disease, and then the authority was limited to the prevention of cholera, yellow fever, smallpox, and plague. In 1893 this authority was extended to cover all infectious and contagious diseases, and provision was made for cooperation with State and municipal health agencies.

Congress recognized the value of military discipline in an organization which had to combat epidemic diseases, and in 1889 authorized the organization of the Marine Hospital Service along military lines, with officers holding commissions in grades similar to officers of the medical department of the Army.

In 1902 the name of the organization was changed to "The Public Health and Marine Hospital Service," and in 1912 this name was changed to that now borne by the service

While the public health functions of the service had their inception in the prevention of the introduction and spread of quarantinable diseases, their development was largely the result of changes in public opinion Investigative functions began with inquiries into the causes of such diseases as yellow fever and cholera In 1902 the Hygienic Laboratory was established, and to-day this institution is recognized as one of the foremost research centers in the world.

The functions of the service may be summarized as follows:

1. Furnishing medical service to American seamen and other beneficiaries
2. Protection of the United States from the introduction of disease from without.
3. Prevention of the interstate spread of disease and suppression of epidemics.
4. Cooperation with State and local boards of health as well as with Federal agencies in health matters.
5. Investigation of diseases of man.
6. Supervision and control of biological products.
7. Public health education and dissemination of health information.

One of the functions exercised by the service—that of supervision and control of biological products—is of tremendous importance. It means that all viruses, vaccines, therapeutic serums, toxins, antitoxins and analogous products applicable to the prevention and cure of diseases of man are tested by the service for purity and potency. The value of such products supervised by the service in one year is well over $10,000,000.

As organized at present the Surgeon General administers the affairs of the Bureau of the Public Health Service through seven administrative divisions. These are: The Division of Marine Hospitals and Relief, the Division of Domestic Quarantine, the Division of Foreign and Insular Quarantine, the Division of Personnel and Accounts, the Division of Sanitary Reports and Statistics, the Division of Scientific Research, and the Division of Venereal Diseases.

Division of Scientific Research

Save for his superior mental capacity, man enjoys no particular advantage over other forms of life in the struggle against disease Therefore his most important weapon in that struggle is the application of that mentality to methods of promoting his health. The most effective method of that application devised so far is scientific research through the experimental method

Granted that the necessity for research exists, the question then presents itself as to whether or not the Government should engage in research. Experience and reason both command an affirmative answer.

While it is true that in the United States as elsewhere a large amount of research connected with the safeguarding of public health is carried on by private agencies, there are, nevertheless, compelling reasons why the Government itself should be represented in this field.

A careful analysis will show that by far the greater part of the research work conducted under private agencies is directed to the solution of problems that are almost entirely local or problems pertaining to curative rather than to preventive medicine. On the other hand, the Government, being interested in the welfare of the entire population, concentrates its efforts upon problems affecting large groups and upon preventive rather than curative methods. Occasionally there is an overlapping, as in the case of syphilis, where to cure one case is to prevent another.

The Government also has a duty to perform in checking up on the results of outside research to determine whether or not much of this information can be recommended for general guidance and in formulating scientific information for administrative purposes. Then, too, there are certain problems which no private agency is equipped to solve. These are problems requiring observations widely distributed in a geographic sense and other problems which can be solved only by concentration of many different research activities working in cooperation and simultaneously. In addition to all of these reasons, there is, of course, the Government's obligation to promote the welfare of the people—an obligation which is not shared by outside private agencies, which, properly enough, have their own ends in view in many of their activities.

Recognizing the necessity and propriety of governmental research in the public health field the Congress in the act of August 14, 1912, provided that:

"The Public Health Service may study and investigate the diseases of man and conditions influencing the propagation and spread thereof, including sanitation and sewage and the pollution, either directly or indirectly, of the navigable streams and lakes of the United States."

An earlier act of Congress had established the Hygienic Laboratory in Washington, the scene of an important part of the research activities carried on by the Division of Scientific Research of the Public Health Service.

The scope of the division's activities may be described as follows:

1. The investigative functions have been extended to include every major topic of public health interest The approaches to the problems have been from several standpoints—(*a*) of the basic sciences in the laboratory; (*b*) of clinical study; (*c*) of epidemiology; (*d*) of sociology and economics; (*e*) of vital statistics; (*f*) of public health administration.

2 The control function (biologic products), authorized by the act of July 1, 1902, has extended to the limitations of the act in so far as permitted by the funds appropriated. It has included researches necessitated by adequate control. The control of biologic products necessitates inspections in many parts of the United States and in those European countries where these are necessary.

The activities of this division have carried its agents into every State in the Union, the insular possessions of the United States, Mexico, and several countries of Europe.

In addition to those activities which it carries on independently the division does not hesitate to cooperate with other agencies doing work within its field. In exchange for opportunities for research and access to material the division always stands ready to cooperate with any Government agency in the solution of problems relating to public health, subject to the consideration of relative importance in terms of service to the country and also subject to limitations of funds and personnel. This same readiness applies to nongovernmental organizations with the additional considerations of their aims, purposes, and good faith.

At various times the division has cooperated in research with many public and private agencies, including the Bureau of Mines, the Bureau of Standards, Johns Hopkins University, Yale, Harvard, the National Research Council, many manufacturing and industrial organizations, and the State boards of health of the various States of the Union.

A topic is considered eligible for investigation by this division provided it is of public-health interest, and if funds and personnel are available, under the following circumstances:

1. The subject is of widespread significance and no adequate solution is at hand.

2. Other agencies are not studying the subject, or at least not from the standpoint of public health.

3. The subject threatens to become of widespread importance, rendering anticipatory research advantageous.

The principal activities of the division at present include:

Studies of a number of diseases of man, including cancer, clonorchiasis, encephalitis lethargica, goiter, influenza, leprosy, malaria, nutritional diseases, pneumonia, Rocky Mountain spotted fever, trachoma, tuberculosis, tularæmia and typhus fever; investigations on the subjects of administrative health practice, child hygiene, drug addiction, industrial hygiene and sanitation, mental health, milk, morbidity, oxidation reduction, stream pollution and salt-marsh mosquito control; and studies and inspections required for the regulation of interstate traffic in biologic products.

Division of Marine Hospitals and Relief

The Division of Marine Hospitals and Relief is part of the Bureau of the Public Health Service which performs the functions for which the service was established by Congress in 1798. At that time, indeed, the organization was known as the Marine Hospital Service. the idea of a Federal health department was something entirely outside the ken of political thought in the infant Nation.

From time immemorial it has been the law of the sea that vessels must provide medical attention for seamen. Hence, when the Congress wished to encourage the embryonic merchant marine of the newborn Republic, one of the means it took was to relieve the ships of the burden imposed by this requirement

Thus it came about that some of the earliest institutions established by the Federal Government were marine hospitals. Marine hospitals antedated naval hospitals and, in the early days, the former took care of officers and men of the Navy. The first marine hospital in Boston, which, incidentally, was the first general hospital in that city, furnished hospital care for wounded who fought under John Paul Jones

The earlier hospitals were primitive affairs according to modern standards. Medical knowledge has advanced greatly in the past 137 years and the marine hospitals have kept abreast of the times. Attending specialists augment the regular staff of medical officers; trained graduate nurses and dietitians, as well as skilled physiotherapy aides, are employed. The medical and surgical work of the marine

hospitals compares favorably with that of representative hospitals in their respective ports, although some of the hospitals are architecturally obsolete For instance, the present marine hospitals at New Orleans and San Francisco, built just after the Civil War, were products of a school of thought and medical knowledge which held that hospitals must be of the flimsiest possible construction so that as soon as they became infected with hospital gangrene or some similar unwelcome visitor, the building could be burned. These two hospitals, "built to burn," are still standing awaiting sufficient funds to substitute fireproof structures. It is a marvel that they have not long since realized the purpose for which they were built. Probably, the only reason these structures have not been burned is the ceaseless care with which they are guarded by a well-disciplined personnel. In all the years of the existence of marine hospitals not a single patient has been burned to death in a hospital fire—a most surprising record, particularly when the type of some of the early structures is considered Hospital fires have occurred, however; the first Chicago Marine Hospital was destroyed in the great fire of 1871.

The marine hospitals in the beginning were financed through a tax of 20 cents per month, later increased to 40 cents, deducted from the wages of each seaman and collected by the collector of customs. Subsequently this was replaced by a tonnage tax and finally by direct appropriations out of the Treasury. It has been nearly 50 years since the 40 cents per month tax was collected, but aged sailors still sailing the seas and coming into the hospitals recall that they helped build these institutions out of their own wages.

There are 25 marine hospitals to-day in various ports of the United States. The policy of the Government is to build such hospitals only in ports where it is more economical to have Government-owned buildings than to provide hospital care through contractual arrangements with private institutions. Provision for the care of seamen is made in 150 ports of the United States and insular possessions and there are always between 3,000 and 4,000 sailors in hospitals under the supervision of this division.

The growth of the merchant marine and the general increase in the population of the United States have been reflected in the expansion of marine hospital functions. More than 300,000 persons annually now apply for treatment or examination at these hospitals or out-patient offices. There were furnished last year 1,321,309 patient days of hospital care and 572,139 out-patient treatments, the latter item including the vaccination of 35,719 beneficiaries against smallpox and typhoid.

Dentistry, a modern hospital necessity, is supplied by 30 full-time dental officers who last year gave to 30,811 beneficiaries 110,320 treatments. In the marine hospital laboratories 192,308 bacteriological

and other clinical laboratory examinations were made, and 37,535 X-ray exposures made for diagnostic purposes.

The marine hospitals are open to personnel of the Army, Navy, and Coast Guard, to patients of the United States Veterans' Bureau, and to injured employees of the United States Government receiving care under the supervision of the Employees' Compensation Commission The hospital on Ellis Island, New York City, is operated chiefly for diseased immigrants detained by the immigration authorities It is also the policy of the Government to allow foreign seamen to enter marine hospitals as pay patients when a request is made on their behalf by the master of a foreign vessel or by a foreign consul

It costs a little more than $5,000,000 per year to maintain the marine hospitals. Approximately $500,000 a year is returned to the Government for the various classes of pay patients, including immigrants. The average cost of operation per patient per day has been reduced from $4.08 in 1923, $3 84 in 1924 and $3.80 in 1925 to $3.71 for the fiscal year ended June 30, 1926. This is lower than the average cost of operation of hospitals belonging to the Army, Navy, or the Veterans' Bureau, and considerably less than that of civilian hospitals furnishing equivalent services and having trained nurses and salaried staffs of physicians and surgeons.

An idea of the costs of operation may be obtained from the figures showing some of the expenditures for hospital supplies during the past fiscal year. Some of the items are adhesive plaster, $4,347.45; salvarsan and other supplies used in the treatment of syphilis, $6,410.43; gauze and surgical dressings, $17,536.28; ether and other anesthetics, $1,786.98; catgut ligatures for surgical operations, $2,656.23; soap, $25,855.23; clinical thermometers, $2,714.55; X-ray films, $15,707 65; insulin, $1,794.

The item for the purchase of insulin suggests the remarkable progress which has been made in the treatment of diabetes since the use of this remedy was initiated. Since its use was introduced there has been a constant increase in the number of diabetes cases admitted to marine hospitals and a constant decrease in the number of deaths. The figures are, 1923, 78 cases and 23 deaths; 1924, 97 cases and 12 deaths; 1925, 108 cases and 9 deaths; 1926, 110 cases and 5 deaths. The figures refer to fiscal years.

Starting out merely as an agency doing relief work for seamen, the Public Health Service has expanded and acquired manifold and varied functions. It was natural for quarantine duties to be added, together with other functions relating to the safety of ships and the welfare of their personnel. It became the agency which examines applicants for license as pilots and other ships' officers who must pass satisfactory tests for vision, color vision, and hearing. Lighthouse keepers are also required to pass similar examinations before they are

appointed. The Public Health Service must also vouch for the physical ability of sailors qualifying as "able-bodied seamen," of which the crew of an American ship must have not less than 65 per cent; and since ships' officers must be versed in first aid before licensed by the Steamboat Inspection Service, courses of instruction have been organized in 43 ports where medical officers give the necessary instruction preliminary to examination of the candidates in this subject. The physical examinations, which number nearly 100,000 yearly, include those of the United States Coast Guard recruits, the United States Civil Service, Pension Bureau, and Army training camps

All medical service for the Coast Guard is furnished by the United States Public Health Service, which also sends its medical officers with the cruising cutters on the Alaska seal patrol and the North Atlantic ice patrol, and wherever else these ships may go.

Alcoholic liquors and narcotics required for medicinal use on board any American or foreign ship in an American port are purchased or otherwise authorized by an officer of the Public Health Service in amounts according to the governing medicinal needs.

At Fort Stanton, N. Mex., a marine hospital is maintained for tuberculous patients where provision is made not only for medical treatment but also for employment of patients who are approaching fitness for discharge. These latter are employed for several months in order to make sure that their return to health has been permanent. Only those tuberculous patients who are expected to recover are sent to Fort Stanton; the others are treated in various port hospitals.

The National Leper Home at Carville, La., is operated by the Public Health Service. There are now about 270 patients there, culled by State health officers from the population at large. Treatments by chaulmoogra oil, X ray and mercurochrome, by violet ray and other lights, as well as by hydrotherapy and many other agents, have yielded encouraging results and some cures are effected. The radio, baseball, moving pictures, a library, a school and religious solace furnished by chaplains and chapels for both Catholics and Protestants bring some measure of contentment to the inmates. Leper patients physically fit are employed by the Government at nominal pay in light occupations at this institution, thus providing some diversion and a small means of income to those unfortunates, who are, however, clothed and otherwise well cared for at Federal expense.

From 1919 to 1922 the Public Health Service was designated as the principal agency to care for World War veterans in need of hospital care. To do this the service rented hospital space, converted hotels and other buildings to hospital uses, and, in general, did the best it could to meet an unprecedented situation which confronted it unexpectedly.

In 1922, when Congress assigned this work to the Veterans' Bureau, the Public Health Service turned over 57 hospitals with 17,500 beds, 900 physicians, 1,400 nurses, and 9,200 employees More than a million veterans passed through these hospitals during the time they were under the supervision of the Public Health Service

The marine hospitals, in addition to their other functions, may be considered as a second line of defense behind the foreign quarantine division in preventing the entry of quarantinable diseases into the country. For example, only recently, a seaman at New Orleans applied to the marine hospital there for treatment. It was found that he was suffering from bubonic plague. The quarantine officials were notified at once and his ship was thoroughly fumigated to destroy the rats and fleas through which this disease is transmitted Under similar circumstances a seaman who had been admitted at San Francisco was found to be suffering from smallpox. Such cases are rare, of course, because the quarantine regulations are most efficiently administered.

Recently the marine hospitals have made it a practice to transmit medical advice to ships at sea by wireless. These messages must, for the present, at least, be transmitted through commercial stations, but the latter have been very generous in giving this service without charge. It frequently happens that the advice thus given besides aiding the patient enables the ship to continue on its course instead of putting in at some unscheduled port with consequent loss of valuable time and great inconvenience to passengers.

Division of Foreign and Insular Quarantine

The right of one community to protect the health of its members by excluding outsiders afflicted with communicable diseases has been recognized and exercised since the dawn of history So well established is this right that the principle has never been questioned in all of the countless controversies which have raged over its application to specific cases Quarantines have been enforced as to individuals, cities, and nations, by methods ranging from religious tabus of the primitive races to the bayonets and warships of the modern and more materialistic peoples.

Geographically, the quarantines of antiquity and, indeed, up to very recent times, were comparatively limited. The methods by which the great scourge diseases were transmitted were not understood and, in many cases, it was thought that so long as physical contact with the diseased persons was avoided, the disease would not spread.

Two chief factors have combined to increase the geographic area of quarantines in modern times. The first is the discovery of the methods whereby diseases are transmitted, and the second is the

development of means of transportation which facilitate the transportation of disease bacilli as well as persons and property.

Thus it comes about that all modern civilized States now recognize the need for national quarantines and national agencies to enforce the quarantine regulations. The United States, due to the peculiar relationship between the individual States and the Federal Government, was one of the last of the great powers to put a national quarantine system into operation. In the early years of the Nation's existence the contention was advanced—and upheld by the courts—that the imposition and enforcement of quarantine regulations was an exercise of the police power reserved to the States

Quite early in its history the Public Health Service was authorized to advise and cooperate with the State health authorities Gradually this developed to a point where the various States came to realize the advantages of a central system for foreign quarantines and one by one the State legislatures voluntarily turned that function over to the Federal authorities The Public Health Service now administers the quarantine at all ports of the United States, and this work is done through its Division of Foreign and Insular Quarantine

This division has two major functions—prevention of the entrance of diseases from foreign countries into the United States, and medical inspection of aliens applying for admission to the United States as immigrants. In the exercise of the first-mentioned function the division has jurisdiction over all ships and all persons, citizens, and aliens coming into American ports from abroad. The second function, of course, has to do with aliens only. In practical operation it has been found necessary to separate the two functions from an administrative standpoint. This was done because in its inspection of immigrants the Public Health Service acts, more or less, as the agent for the Immigration Service of the Department of Labor. The work of the Health Service ceases, with respect to an immigrant, when he has been certified to the immigration authorities as either admissible or inadmissible physically. On the other hand, the Public Health Service has entire charge of the quarantine work at the ports.

There are three lines of defense against the quarantinable diseases cholera, plague, yellow fever, typhus fever, leprosy, smallpox, and anthrax. The first line consists of the public health physicians stationed abroad and working in cooperation with the consular officers to prevent diseases in any form from embarking on vessels bound for the United States; the second line is the system of inspection at the various ports of entry; and the third line is the cooperation between the Public Health Service and local health authorities, especially those at ports of entry, in "follow up" work

The Public Health Service, once the diseased person has been admitted to the United States, can control only interstate travel of such person. A system of cooperation has been established with city and State health authorities to follow cases released at the ports, such as diphtheria and other nonquarantiable diseases, and to notify the health officer, who cares for such a person until he is taken over by the local health authorities

Methods of preventing the entrance of quarantinable diseases vary with the diseases, as each spreads by different means and must be blocked accordingly. In the case of cholera, where the avenue of transmission is from person to person via the alimentary tract, the method is to prevent the entrance of any persons suffering from the disease. The work is complicated by the fact that certain persons seem to be immune from cholera themselves but can carry the germs of the disease and transmit them to others. These persons, known as carriers, are more difficult to guard against than persons actually suffering from the disease since the former may be entirely unaware of their condition. Cholera carriers are denied admission to the United States until they are noncarriers, and persons who have been exposed are detained long enough to determine whether or not they have been infected. Cholera, together with all of the other quarantinable diseases except typhus, leprosy and smallpox, has been exterminated in the United States.

Yellow fever, long the terror of the South, is probably the best example which can be cited of a disease almost entirely wiped out of existence by science. At one time there were periodic outbreaks in every southern State and throughout Central and parts of South America, but now the disease is found only in a few isolated districts. The fight against yellow fever was won when it was discovered that the disease is transmitted through one particular species of mosquito, the "*Aëdes ægypti*," generally known as the Stegomyia. Once this was ascertained the problem became the elimination of this mosquito on ship and its control on shore. The Stegomyia can fly but a short distance and breeds in fresh water about houses, which make it exceedingly vulnerable to careful control. Since the discovery of the method whereby yellow fever is transmitted, there has been only one outbreak of it in the United States, in 1905.

Plague, another quarantinable disease which claims its victims by the thousands in many parts of the world, is of two varieties—pneumonic and bubonic. The former, while very deadly, has occurred chiefly in Asia, only two outbreaks having occurred in this country. The bubonic variety is an ever present danger for nearly every port in the world. Just as yellow fever was found to be transmitted by the mosquito, so it was found that bubonic plague is transmitted through the combined agency of rats and fleas. The

rats themselves are subject to the plague, the fleas live on the rats until the latter die and then the fleas attack any warm-blooded animal, including man, and pass the disease along Fleas, however, specialize, and different animals have their own species that will live on no other animal except in emergencies Thus, rats have several varieties, and while all of them theoretically can transmit plague, practical observations and experiments now under way indicate that for practical purposes there is only one or possibly two species of fleas that need be considered. Fumigation of ships to rid them of rats and fleas is one of the methods employed, and considerable progress has been made, but in its search for better methods the Public Health Service has developed the rat proofing of ships, which, if successful, will be a surer and more economical way to remove this danger altogether.

Smallpox is now combated at ports chiefly through the use of the immunity reaction, which indicates whether or not a person may contract the disease. This is effective as a method of determining whether a previous vaccination is still effective and still retains its potency. Persons who have not been vaccinated or whose vaccinations are no longer active submit to another vaccination if they have been exposed to smallpox. No coercion is employed to induce persons to submit to vaccination, but if they are not vaccinated they must be detained in quarantine for 14 days. They rarely remain for that period, but ask to be vaccinated. Smallpox has been one of the historic scourges of man for centuries. Since the discovery of vaccination, about 100 years ago, the ravages of this disease have been curtailed to a remarkable degree, and it could be practically eliminated if vaccination were universal, but experience shows that neglect of this preventive is sooner or later always followed by a recrudescence.

Typhus fever is transmitted by body lice carrying the infection from one person to another. Hence, the method employed in fighting it is to destroy the lice. Just after the World War, when typhus was widespread in Europe, and when it was estimated that 3,000,000 persons died from it in five years, it was asserted by those in touch with the situation that the peasant classes of Europe were practically 100 per cent infested with body lice. It was at this time that the steamship companies installed their delousing plants on advice of quarantine officers stationed abroad, and all persons arriving were scrubbed and disinfected, if not scrupulously clean. At present less than one-tenth of 1 per cent of the persons arriving at American ports are found to be infested, and it is reported that on account of the requirements of the United States Public Health Service there has been a great improvement in conditions abroad, particularly in places where body lice had long been accepted as a matter of course.

Anthrax is much less important. It has been demonstrated that this disease has been frequently transmitted to man through infected bristles of shaving brushes Consequently, all shaving brushes imported to the United States must be made from bristles that have been disinfected.

Leprosy, the other quarantinable disease, is treated in a manner somewhat different from the others. It is still the same enigma to science that it has been for centuries. Some progress has been made in the treatment of leprosy through the injection of chaulmoogra oil derivatives, but the nature of the disease and how this treatment is of benefit are still unknown When a leper arrives at an American port he is sent to the Federal Leprosarium at Carville, La , if he is an American citizen If he is an alien he is deported. This disease does not present the problems of rapid incubation and free transmission that occur in connection with the other quarantinable diseases.

Persons found suffering from diseases in the quarantinable group are cared for in the Public Health Service hospitals until danger of transmitting the disease to others is past. Then, if they are American citizens, they are released. If they are aliens they are passed on to the immigration authorities.

In cooperation with the Department of Labor the Public Health Service, through its Division of Foreign Quarantine, makes the physical examinations for all prospective immigrants. During the fiscal year ending June 30, 1926, the officers of the division examined 614,972 applicants for admission and 872,842 alien seamen. Many of these examinations of immigrants were made abroad under the new system inaugurated in 1925, which has eliminated most of the heartaches and suffering of the old system and has excluded the unfit to an extent never before possible.

So far as physical condition is concerned, prospective immigrants are divided into three classes: Class A, those having defects which make them mandatorily excludable under the law; class B, those whose defects are not such as to make exclusion mandatory, but which may interfere with the applicant's ability to earn a living, and class C, those having minor defects which do not affect their admissibility but which are noted, nevertheless.

Division of Sanitary Reports and Statistics

It is a fundamental principle that in any warfare the success of the conflict largely depends upon our knowledge of whether there be an enemy, when, where, and in what numbers he may be found, and so in the fight against disease from a public health standpoint, whether it be municipal, State, national or international, it is of fundamental importance that responsible officials have early, accurate, and com-

plete knowledge as to the presence or absence of the important communicable diseases. In the absence of such knowledge there will be either a lack of vigilance, which may end in disaster, or, what is of vast importance in these days of commercial enterprise and rapid communication, there will be a futile and unnecessary expensive outlay against a supposed danger which does not exist

This has, within the past few decades, been brought out, particularly in the matter of yellow fever. So long as infectible countries, such as ours, knew of the general existence of yellow fever but did not know the exact endemic centers of this disease, elaborate precautions had to be taken at our maritime quarantine stations against all yellow-fever-suspected areas, whereas, at present, with our intelligence service, such precautions have been waived with benefit to commerce

The collection and dissemination of information concerning the prevalence of disease is of increasing importance in this age of speedy transportation facilities For instance, it is possible that a person infected with typhoid fever may, even by motor, traverse the entire width of the country before the completion of the incubation period of this disease.

The division of sanitary reports and statistics of the Public Health Service may well be described as the intelligence office of the Federal health agency, whose intelligence, however, is used throughout the world by other governments, as well as by our own local and State agencies. Broadly speaking, the work of this division has two general phases—first, the collection from all parts of the world, including our own country, of information having a bearing on the maintenance of public health, and, second, the dissemination of this information in such manner and to such persons and organizations as will make it most valuable. Between the collection and dissemination of information there is, of course, the very important work of compilation.

The information employed by the division is secured from many sources, local, State, Federal, and international. To begin with, every consul and consular officer stationed abroad makes a weekly report to the Public Health Service as a part of his routine duties. The reports are made on forms provided by the Public Health Service and bearing a list of the more important communicable diseases. The consular officer obtains reports from health officials of the country to which he is accredited, and from these reports and such other sources as are available he fills in the information required on the form and mails it to the Public Health Service. These reports by mail cover the following diseases: Cerebrospinal meningitis (epidemic); cholera, Asiatic; cholera nostras, cholerine, or gastroenteritis; diphtheria; measles; plague, human; plague, rodent; poliomyelitis (acute anterior poliomyelitis or infantile paralysis); scarlet fever;

smallpox; tuberculosis; typhoid fever (enteric fever, typhus abdominalis); typhus fever (typhus exanthematicus); and yellow fever.

In cases where there is an outbreak of plague, cholera, yellow fever, or typhus fever in his territory the consul promptly cables this information, instead of mailing it. Owing to this method of transmitting information it occasionally happens that a ship which has left a foreign port before one of these outbreaks reaches an American port in ignorance of the fact, and the master of the ship gets his information concerning the disease from the American health authorities.

Cholera, plague, yellow fever, typhus, smallpox, leprosy, and anthrax are classified as quarantinable diseases. This means that when a ship reaches port from an area in which there has been an outbreak of one of them, or with a case of one of these diseases on board, there are special measures of disinfection and segregation which are taken to prevent any spread of the contagion or infection in the United States.

Reports from consular officials abroad are the principal sources upon which the Public Health Service depends for what may be distinguished as its current information on world health conditions. In addition, however, the service receives all of the bulletins and other documents issued by the health section of the League of Nations, the International Hygiene Office in Paris, and similar agencies. Most of these, of course, are at least a month old when they reach the United States, but they are valuable records for statistical purposes.

The United States has what is called sanitary treaties with all of the important nations of the world (International Sanitary Convention of Paris), as well as a regional agreement with Pan American countries (Pan American Sanitary Code). These sanitary agreements, which have the force of treaties, provide for an international exchange of information relating to public health. This means that all of the nations of Central and South America receive regularly all the data on public health gathered by the world-wide information system of the United States, this information being cabled in case of emergency conditions. This is of immense value to some of the small States which do not have their own facilities for such purposes. This activity at the present time is largely an "export" business so far as the United States is concerned, but from some countries reciprocal reports of great value are received.

In the domestic field the Public Health Service is kept informed of conditions by weekly reports mailed in from local health officials in 570 cities of 10,000 or more population. These reports cover the prevalence for their respective territories of the following diseases: Chicken pox, diphtheria (carriers not included), influenza, measles, mumps, pneumonia (all forms), scarlet fever, smallpox, tuberculosis (all forms), typhoid fever, whooping cough, cerebrospinal fever,

dengue, lethargic encephalitis, pellagra, poliomyelitis (infantile paralysis), rabies (in man) (developed cases), rabies (in animals), typhus fever.

The local officials who send in these reports are classified as "collaborating epidemiologists" of the Public Health Service and are paid $1 a year. Their reports are mailed under Government "frank" upon cards provided for that purpose

In addition to the reports mailed in each week from the 570 cities, the service also receives weekly telegraphic reports from health officials of the various States

These reports from city and State officials and from the consular officers abroad constitute the basis of the information contained in PUBLIC HEALTH REPORTS, which is issued weekly by the Public Health Service and sent to nearly 10,000 public health officials, sanitariums, libraries, and institutions throughout this country and abroad.

The reports, beside tabular statements of domestic and foreign conditions indicating the state of public health, contain special articles on various phases of public health work and summaries of current works on sanitary engineering, as well as abstracts of current court decisions affecting public health work. It may be remarked here that the experience of many years indicates that the courts in nearly every instance apply the tests of common sense and reasonableness to acts of public health officials which come before the courts for review.

When there has been an outbreak of some particular disease necessitating special measures by the service, in cooperation with city and State health officials, it is the practice to include in the PUBLIC HEALTH REPORTS an account of these activities.

The editing and distribution of PUBLIC HEALTH REPORTS is one of the functions of the Division of Sanitary Reports and Statistics.

It may be asked, Of what use is all of this statistical and other information? Some may doubt the value of informing a public health official in California of an epidemic of influenza in Massachusetts. But it is axiomatic in public health work that disease can not be prevented unless the health officials know where, when, and under what circumstances communicable diseases occur

The value of reports of this kind was strikingly demonstrated during the influenza epidemic a few years ago. The epidemic originated, so far as the United States is concerned, in Boston and spread westward across the country. It was found that public health officials in touch with the situation could predict almost to the day when cases of this disease would be reported in the Middle Western and Western States along the line of march of the "flu" bacillus. And

19528°—26——2

to be forewarned of epidemics of this character is more than half the battle of combating them.

The Division of Sanitary Reports and Statistics was the first organization to take up the idea of radio broadcasting of talks on health topics on a large scale. These talks are prepared by medical officers of the service and are broadcast from the naval station at Arlington. Multigraphed copies are sent to other broadcasting stations throughout the country, and frequently they are "put on the air" by these stations.

Another function of the division is handling the vast number of requests for literature and information on health topics which pour into the Public Health Service The service now has nearly 2,000 publications which may be sent in reply to such requests. When a request comes in for information not given in any of these publications, an effort is made to refer the inquirer to sources from which he can obtain what he desires. Frequently inquiries on subjects falling within the scope of other agencies of the Government are referred to those offices for reply. Likewise it happens quite often that other departments and bureaus receive requests for information which can be supplied by the Public Health Service. A regular system of interchange of such requests has been worked out. In the course of the last fiscal year ending June 30, 1926, a total of approximately 380,000 copies of publications was sent and individual replies made in response to requests for information.

Division of Personnel and Accounts

Every organization which operates over a wide geographic area needs a central control office, a nerve center, so to speak, which directs the movements of the distant members. So the United States Public Health Service, which has the earth and the air above and the waters, if any, underneath the earth, for its sphere of activity, has a dispatcher's office in the guise of its Division of Personnel and Accounts. It is through this division that each of the more than 8,000 men and women who comprise the personnel of the service came into the organization; and it is through this office that these same men and women are moved about in the great game which the Public Health Service plays with disease as its opponent and the world as its chess board.

Being a mobile organization and required to meet public health emergencies, the Public Health Service is organized and conducted under strict disciplinary rules. This necessitates adequate central control and means to attend to the mechanics of movements and other matters affecting personnel. In fact, there must be some specific office charged with the keeping of records of appointments, promotions, discontinuances, leaves of absence, changes of station,

and maintenance of discipline in accordance with the laws and regulations on the subject It is the Division of Personnel and Accounts which does all these things for the Public Health Service. In addition the division looks after the preparation of estimates of appropriations to carry on activities, recommends apportionments of appropriations in conformity with law, makes allotments to conduct the several activities, and maintains records of all finances and expenditures, including an elaborate system of cost accounting for the manifold operations of the Public Health Service.

The addition of new laws relating to accounting and to reclassification and retirement of employees renders these records essential to the proper administration of public health activities Moreover, the Division of Personnel and Accounts is the property office of the Public Health Service. Every article which the service uses, from a laboratory microscope to a hospital ambulance, must be properly accounted for from the time it is purchased until it is worn out and condemned. It is through this division that all records of property and supplies are maintained and surplus supplies at one station distributed to other stations as may be needed.

If any function of the division is more important than the others it is the recruiting and giving commissioned personnel opportunity for experience in the larger duties they will be called upon later to perform. It was this training and experience that enabled officers of the Public Health Service to make investigations of far-reaching importance By this means, light was thrown on the transmission of yellow fever, the cause of hookworm disease in America was discovered, and tularæmia, a disease peculiar to America, was identified and its method of transmission established Moreover, through experience, officers are able to engage in highly technical investigations affecting the public health. A candidate for appointment in the regular corps is required to pass a thorough examination before a board of medical officers. These examinations are held at intervals in various large cities of the United States for those candidates who, after application, have been invited by the Surgeon General to participate. The examinations consist of oral, written, and laboratory tests necessary to determine the candidate's mental and physical aptitude, as well as professional attainments. The service makes no allowance for the expenses of candidates appearing for examination.

Applicants must be between the ages of 23 and 32, citizens of the United States, graduates of a reputable medical college, and must have served an interneship in an approved hospital for one year, or have practiced medicine for two years. An average of 80 per cent in all branches is required for admission to the service. Appointments are made by the President on recommendation of the Surgeon

General and subject to confirmation by the Senate. When this confirmation has been given, the candidates become assistant surgeons and are assigned to duty.

At this point in the career of the young Public Health Service officer it becomes the duty of the Division of Personnel and Accounts to see to it that he is given such assignments as will provide him with a well-balanced experience, necessary to the solution of larger problems while he remains in the service. So far as practicable, during the first four years he is in the service, the young officer is detailed for duty at a marine hospital, a quarantine station, an immigration station, Hygienic Laboratory, and in public health work in the field, in the order named.

The length of time the officer spends on each detail depends upon his previous training and the exigencies of the service. Where possible and within limits, consideration is given to the preference of the individual officer.

After four years' commissioned service, an assistant surgeon is eligible for promotion, after examination, to the grade of passed assistant surgeon. Passed assistant surgeons after 12 years' commissioned service may be promoted to the grade of surgeon. Promotions to the grades of senior surgeon and Assistant Surgeon General are made as vacancies occur by promotion of the ranking surgeon or senior surgeon, respectively. Before such promotions are made, the officer is required to pass a physical examination, and his record is reviewed by a board of officers.

The pay of commissioned officers of the Public Health Service ranges from $2,699 for an assistant surgeon to $7,179 for an Assistant Surgeon General, both without dependents. For officers having dependents, the salary range is $3,158 to $7,200. A Surgeon General receives $7,500 if he has dependents, and $7,179 if he has none. These salaries are established by the same law which fixes those of officers of the Army and the Navy. The grades are comparable to those of medical officers of the Army and Navy. Advances in pay in higher grades are dependent, however, upon length of service rather than promotion in rank. By reason of legislative restrictions of long standing, promotions in the higher grades are almost negligible.

All other personnel of the Public Health Service is selected from lists of eligibles established by the Civil Service Commission under civil service law and regulations. The diverse system of appointment sometimes presents difficulties when men of special scientific attainments are required for specific work involving change of station. It would be highly desirable from the standpoint of the Public Health Service if all medical and scientific personnel subject to emergency and liable to changes of station were selected in the same manner as the commissioned officers. The adoption of this policy would pro-

mote scientific investigations and be in the interest of efficient administration.

For administrative purposes the Public Health Service divides the country into six sanitary districts with a medical director assigned to each district. Through these directors the Surgeon General keeps in touch with State and local health authorities, universities, industries, and other interests favorably affected by public health work. These directors also make inspections of service stations and activities with a view to their coordination, investigate administrative difficulties, and devise means for the prevention and suppression of epidemics liable to occur within their districts. The ordinary routine of stations is handled by the officers in charge. The district directors accordingly act largely in an advisory capacity without the necessity of considerable personnel.

The present is an age of specialization, particularly in the field of medicine, and thus it happens that within the service there are groups of officers having special qualifications for solving particular problems. Some of these officers may be devoting their time regularly to investigations of communicable diseases, nutritional diseases, the health hazards of industry, or other public health problems. But when an emergency arises in any district, selection and detail of personnel must be made to meet it In such cases the Division of Personnel and Accounts is the channel through which the Surgeon General transmits his orders. All epidemic situations are met in this manner. These movements of personnel are limited as much as possible, however, by the policy of having officers with all-round training distributed here and there so as to meet emergency situations as they arise.

During the fiscal year ended June 30, 1926, there were many extra routine demands upon the Public Health Service for the services of specialized personnel. There was the extension of the immigration inspection work to European ports, the fight against the spread of bubonic plague in California, the tetraethyl lead investigation, the investigation of the shellfish industry, investigations and administration of methods to safeguard milk supplies, and advisory work with the Office of Indian Affairs. All of these demands required the selection and disposition of qualified personnel.

In addition, there are constant demands from private and semipublic organizations for assistance and instruction in public health matters. Officers are detailed, therefore, to attend meetings of associations for the promotion of public health. It is the policy of the service to supply speakers wherever possible and where the importance of the occasion merits, for the dissemination of public health information and to cooperate with and aid State and local authorities in the solution of public health problems which arise in connection with

administration. It is necessary for some agency to evaluate for the Surgeon General the relative importance of the demands received. This decision devolves largely upon the Division of Personnel and Accounts because of its knowledge of the availability of officers from day to day.

Division of Domestic Quarantine

"Quarantine," by which is meant any forced stoppage of travel, communication, or intercourse on account of contagious or infectious diseases on land or by sea, was probably the earliest known method used to prevent the introduction of disease. Isolation and quarantine, in the sense of holding vessels and people until danger of disease was supposed to have passed, were naturally in use for ages before the actual modes or methods for transmission of communicable disease were known, and during the colonial period each of the colonies had more or less adequate provision for its protection from the introduction of exotic disease from abroad.

When the United States came into being, with its unique system of balance between Federal and State powers, health matters, which are universally regarded as police powers, were, by inference, left to the control of the several States. The control of foreign and interstate communication, however, was, of course, given to the Federal jurisdiction. Among the early laws passed in the first decade after the Constitution were those enjoining Federal officials (Army, revenue cutter, customs, etc.) to assist the several States in the enforcement of their quarantine laws. There were few or no laws other than local providing for the possibility of the interstate spread of disease With the introduction of the railroad and steamboat, with consequent increase in travel and communication, the necessity for coordinated effort was seen, and by consent of the States, and under the commerce clause of the Constitution, laws were passed providing for Federal control both of interstate and maritime quarantine functions.

The Domestic Quarantine Division of the Public Health Service came into being in 1910. Its functions may be summarized as follows:

1 Enforcement of the interstate quarantine regulations of the United States.

2 Development of State departments of health, especially divisions of communicable diseases and sanitary engineering.

3. Control over water supplies used for drinking and culinary purposes on railroads, vessels, and other interstate carriers.

4 Sanitation of the national parks in cooperation with the National Park Service.

5. Measures for the control and prevention of trachoma.

6. Studies of and demonstrations in rural sanitation.

7. The annual conference of State and Territorial health authorities with the Public Health Service.

8. Other contacts with State and Territorial health officials relating to health administration.

Some idea of the extent of the duties imposed upon the division by the requirement that it enforce the interstate quarantine regulations may be gleaned from the first paragraph of these regulations, which reads:

"For the purpose of interstate quarantine the following diseases shall be regarded as contagious and infectious diseases within the meaning of section 3 of the act approved February 15, 1893: Plague, cholera, smallpox, typhus fever, yellow fever, typhoid fever, paratyphoid, dysentery, pulmonary tuberculosis, leprosy, scarlet fever, diphtheria, measles, whooping cough, epidemic cerebrospinal meningitis, anterior poliomyelitis, Rocky Mountain spotted or tick fever, gonorrhea, chancroid, anthrax, influenza, pneumonia, epidemic encephalitis, septic sore throat, rubella, and chicken pox."

And paragraph 2 of the same regulations provides that:

"Any person or thing, either living or dead, which has been unduly exposed to or in intimate contact with or is infected with any of the diseases enumerated in section 1, except as otherwise provided in these regulations, shall be regarded as contagious or infectious until the contrary has been proved, and if found in any car, vessel, vehicle, or conveyance undergoing interstate transportation, shall be subjected to such inspection, disinfection, or other measures as may be necessary to prevent the spread of the infection from them"

It will be appreciated that these regulations impose an undertaking of considerable magnitude upon the Division of Domestic Quarantine The regulations cover almost every conceivable situation which might arise in connection with the travel of persons suffering from communicable diseases and the travel of things subject to infection. Provision is also made for the sanitation of interstate common carriers and for the supervision of drinking water and food supplies used on such carriers.

One of the activities of the Public Health Service in connection with interstate travel is the sanitary control over all water supplies used for drinking or culinary purposes on interstate carriers. It is obvious that this is a tremendous task. The water included in this description comes from more than 2,800 sources. Control over this supply from a sanitary standpoint is practicable only because of the cooperation given the Public Health Service by the State and city health authorities. There are many indirect results from this function of the Public Health Service. It has been found that when the water supply of a certain city has been adjudged unfit for use on trains in interstate traffic, these cities are usually quick to

improve their water supply. The local citizenry is prone to feel, and quite properly, that what is not good enough for the traveler passing through their city is not good enough for the home folks.

Sanitation in the national park reservations is a most important phase of the work of the Domestic Quarantine Division. Tourists from every State in the Union visit these parks each year, and if proper precautions were not taken the parks might easily become national focal points of disease distribution. Disposal of sewage and protection of water supplies are the principal subjects with which the public-health officials have to deal in the national parks.

The suppression of epidemics naturally falls within the jurisdiction of the Domestic Quarantine Division. An outbreak of bubonic plague at Los Angeles, Calif., in recent years was suppressed by an active campaign against rodents combined with extensive rat proofing of buildings and the elimination of rat harborages. Similar steps against the same disease have been effective at San Francisco, Oakland, Calif.; New Orleans; Pensacola; Galveston and Beaumont, Tex. The ground squirrels of California have been found to be carriers of the disease, and squirrel-free zones have been maintained around certain ports to prevent the infected squirrels from coming in contact with city rats and causing an extensive plague infection—first of the rats, and later of human beings.

It was the Division of Domestic Quarantine which directed the investigation of the shellfish industry during the past year following upon an outbreak of typhoid fever attributable to infected oysters. The investigation resulted in the adoption of methods to prevent infection of the oysters through cooperation with the shellfish industry and State health authorities.

Rural sanitation is a subject in the development of which the Public Health Service takes an active interest through studies and demonstration work. The counties have been encouraged to work in this field in the past through allotments from Federal funds. The local communities now spend about $9 for this work for every dollar contributed by the Federal Government. Demonstration projects in which the division is now participating include: General sanitation, child and maternity hygiene, tuberculosis control, acute communicable disease control, and school hygiene.

For the fiscal year ending June 30, 1926, the appropriations for the work of the Domestic Quarantine Division totaled approximately $450,000.

Division of Venereal Diseases

Back in 1911 the Public Health Service wanted to do something which, it hoped, would bring about a reduction in the prevalence of venereal diseases among the patients in the marine hospitals. At

that time—and for that matter to-day—about 22 per cent of the work of the marine hospitals had and has to do with venereal infections of one kind or another

So, in 1911, the Public Health Service prepared a booklet containing the facts then known about venereal diseases, stated in plain and simple language The intention was to distribute the booklet among the seamen and others who were cared for in the marine hospitals.

The booklet was sent to the Treasury Department for approval and was promptly sent back with a message that it contained matter which was indecent and improper for the Government to print. And that attitude was sustained by higher officials and the booklet was not printed

However, as far back as 1875 the problem of venereal diseases, their prevention and control, was considered by the United States Public Health Service The annual report for 1875 contained a number of recommendations for the prevention of the introduction of syphilis and gonorrhea into the United States, and suggestions for the treatment of those already infected, which are as germane to the problem to-day as they were at that time "If these regulations were adopted," the report states, "a better sanitary as well as moral state of society would prevail generally."

Nearly 40 years elapsed before the medical and quarantine measures recommended by the service for the control of these diseases had been adopted generally in the United States.

Ehrlich discovered salvarsan in 1910, which discovery, more than any other one thing, resulted in tangible and effective measures for the control of syphilis. The Public Health Service secured the first shipment of this drug to the United States and cooperated in its first administration in this country.

The World War brought the country to a state of mind in which it was willing to look reality in the face, and the Government assumed its share of responsibility of informing the public frankly concerning the nature and prevention of venereal diseases and in applying medical and other measures of control.

Early in the war the Public Health Service participated with other agencies in a campaign for the protection of the armed forces undergoing training at the various cantonments On January 2, 1918, active steps were taken for the official organization of a plan for the nation-wide control of these diseases. Overtures were made to each of the State boards of health for the purpose of enlisting the forces of these organizations. The responses were very encouraging, and by May 24, 1918, 32 States had undertaken systematic efforts to control the spread of venereal infections.

A more concerted effort for the control of these diseases was made possible by an executive order of July 1, 1918, which placed all

Federal health activities other than those of the Army and Navy under the supervision and control of the Public Health Service. On July 9 Congress passed the Chamberlain-Kahn Act creating in the Public Health Service a Division of Venereal Diseases, and appropriating more than $4,000,000 for use during the two following fiscal years to carry out the duties imposed by this act Under the provisions of this act the functions of the division are as follows:

(1) To study and investigate the cause, treatment, and prevention of venereal diseases.

(2) To cooperate with State boards or departments of health for the prevention and control of such diseases within the States, and

(3) To control and prevent the spread of these diseases in interstate traffic.

A tremendous impetus was given to venereal-disease control work as a result of the interest and leadership of the Public Health Service in this movement. During the first 12 months after the passage of this act every State in the Union except four was prosecuting vigorous measures for the control of venereal diseases in accordance with the cooperative plan outlined by the Public Health Service, and at the present time all States are conducting venereal-disease control programs.

It is interesting to compare the attitude of the Government toward venereal-disease control work in 1919 with that of 1911. As a part of the educational work carried on by the Division of Venereal Diseases the country in 1919 was being furnished with millions of educational pamphlets and informational bulletins far more frank in their treatment of the serious subject of venereal diseases than the modest booklet suggested in 1911, which had been deemed indecent and improper for the Government to publish.

In this cooperative endeavor medical, educational, and law-enforcement activities were featured. An important feature in the control of venereal diseases has been the provision of facilities for the treatment of indigent persons suffering from these diseases as the best means of preventing their future spread. More than 900 cooperative clinics have been established by States, counties, cities, and institutions where treatment is given free or at a nominal charge. A total of 915,638 patients has been admitted and 13,835,321 treatments have been given at these clinics.

These clinics have, since 1918, made 1,959,446 Wassermann tests and 1,409,089 microscopic examinations for gonoccocus infection. Nearly every State board of health provides laboratory facilities to aid the physicians in diagnosing these diseases.

Many cases affected with a venereal disease never seek treatment by a physician, and all physicians do not report cases under their

care, but 2,800,000 cases of venereal diseases have been reported to State health departments during the past eight years

One of the most valuable phases of modern public-health effort has been the educational campaign in its attack on venereal diseases. The history of measures for the control of no other disease reveals that public enlightenment has proceeded so rapidly, with the result that a wholesome attitude toward matters of sex is being developed.

The educational work may be divided into two groups—general public educational work and a specific program of sex education to be carried on in schools and colleges As a part of the educational program the service has prepared more than 100 different publications, and over 30,000,000 copies of such publications have been distributed. Seven card exhibits for use in public gatherings have been prepared and widely used Stereopticon slides and posters have been prepared and displayed. In cooperation with State boards of health arrangements have been made to send lecturers to speak before many audiences, giving them essential information on the nature of venereal diseases and methods of their prevention and control.

To encourage the program of sex education in the schools the service has prepared bulletins giving outlines of courses, exhibits stressing physical fitness, and a 12-reel motion-picture film depicting the story of the reproduction of life, the prevention of disease, and rules of personal hygiene.

Sex education includes not only instruction concerning the reproductive function but all teaching and training in the home, church, and school which tends to form normal and wholesome attitudes and ideals in regard to sex and to shape character and conduct in accordance with such attitudes and ideals.

Several studies have been made of the status of sex education in schools. The last one, in 1925, showed that remarkable progress has been made in the inclusion of approved methods of sex education.

A successful effort has been made to secure essentially uniform laws throughout the United States concerning the control of venereal diseases. All States now require these diseases to be reported and control measures are applied in a manner similar to other contagions. Under certain conditions cases which continue to spread the disease are quarantined.

Most States have laws forbidding the sale of "quack" remedies for venereal treatment. Uniform laws and ordinances have been adopted governing the control of prostitution and making the transmission of venereal diseases a crime. These laws, however, should be enforced in a more satisfactory manner.

The study of the cause, treatment methods, and the prevention of venereal diseases has occupied the attention of the Division of

Venereal Diseases. Various investigations have been made which have been of great value in promoting more effective measures of prevention and control.

Investigations have been made of venereal-disease prevalence among various groups of persons as regards sources of infection, age, and other factors. It is interesting to note that a considerable proportion of these diseases, particularly syphilis, are acquired innocently.

The division also serves as a clearing house of knowledge regarding methods of venereal-disease control in foreign countries Information gathered by officers of the Public Health Service is made available to the health officials of the States and to others interested.

Some of these reports from abroad are quite significant In Denmark, for example, where for 116 years the Government has required all persons infected with a venereal disease to submit to treatment supplied free by the Government, it has been found that syphilis has decreased by approximately 33 per cent in the past quarter century. Gonorrhea also showed a decline during that period, though the fall was not so great.

In order to provide facilities for the study of practical problems connected with clinic management, methods of treatment and prevention, the Public Health Service in 1920 established in cooperation with the Interior Department a clinic at the Hot Springs National Park. At this clinic various new drugs have been given practical tests to determine their relative efficacy in producing a cure, and much practical knowledge concerning clinic management has been gained, and this information has been given to the State venereal disease-control officers.

Owing to the reduction in the appropriations for the division, which for the present year amount to $75,000, the venereal-control activities have been considerably curtailed. Since the fiscal year 1925 no funds have been available for allotment to States for cooperative work. As a result, considerable decrease in the activity of many of the States is noticed, although a fair proportion of them are carrying on an active venereal disease-control program.

The following figures indicate the extent and importance of the work of the Division of Venereal Diseases: For the fiscal year 1925 the service received reports of 200,584 cases of syphilis, 165,523 cases of gonorrhea, and 6,706 cases of chancroid. For the fiscal year 1926 reports from the same sources were: Syphilis, 215,547; gonorrhea, 166,656; and chancroid, 7,129. In 1925, 495 clinics reported 62,543 admissions for syphilis, 39,636 for gonorrhea, and 2,843 for chancroid infections. The encouraging factor in the situation is the increased interest which has been aroused among State and local authorities and the public in general. The nature of the diseases makes it certain that the battle will be a long one.

PUBLIC HEALTH ENGINEERING ABSTRACTS

The Destruction of Rat Fleas by Heat on Board Ship.—R. K Shaw, J. Roy. Nav. M. Serv., 1925, v. 11, 255–60 (3 refs). (Abstracted by M. E. Delafield.) From *Bulletin of Hygiene*, vol. 1, No. 2, February 1926, p. 159.

"This investigation was conducted on board H. M S *Endeavour* off the West Coast of Africa with a view to discovering a convenient and certain emergency method of destroying rat fleas in clothing and bedding Seven experiments on about 60 rat fleas were performed. The fleas were placed between blankets or on their surface and exposed to a hot atmosphere, the site in most cases being the engine room, port side, over the water-feed tank. The results indicate that all rat fleas are destroyed in a dry blanket, if folded not more than twice, by exposure to 110° F. for three hours, such a temperature being constantly present in this engine room while at sea. The fleas were found, however, to withstand a high temperature for a prolonged period if kept moist.

"This method of killing fleas has proved to be of practical value in such a ship as the *Endeavour*"

Antimalarial Operations on the Eastern Bengal Railway—Khulna Branch., T. H. Bishop, chief medical officer, Eastern Bengal Railway, Calcutta. *Indian Medical Gazette*, vol. 61, No. 7, July, 1926, pp 337–343. (Abstract by J. A. Le Prince.)

The author thinks three factors should be considered in antimalaria operations by railways: (1) Results achieved may be in part reduced in value by adjacent conditions close to railroad premises; (2) by the large infective focus or group that harbor malaria parasites and feed the mosquito carrier; (3) and by the group of persons who by careless habits allow themselves to be infected.

He considers the antimalaria campaign instituted by the St. Louis Southwestern Railway of the United States as the most successful disease-prevention campaign (after the Panama Zone control) where the mosquito factor was considered, and that a somewhat similar campaign might be possible and might yield good results along the Eastern Bengal Railway.

The campaign conducted included 29 stations, was in charge of four traveling medical officers who visited each family in railway quarters once weekly, made necessary examinations, and so far as possible saw that the course of treatment laid down was carried out. In the families of employees Indian nurses were provided.

Each medical party consisted of a medical graduate, an Indian nurse, and an instructional sanitary "Jamador" to point out things that could be done on a small scale, such as control of small nearby Anopheles sources, cleaning undergrowth, removing garbage, etc.

Of the railway population of the Khulna branch, 2,000 persons, 38 per cent, were treated for malaria by the visiting medical officers. In a single season, of 514 cases of primary malaria 306 were apparently cured and 208 were relapses or reinfections.

The writer thinks that night duty and lack of regular diet are important factors in increasing susceptibility to malaria The percentage of malaria cases to population at 29 stations on the Khulna branch varies from 18 to 68 per cent, but where station forces are small one case gives a high percentage rate. The stations are frequently located close to swamps, and Anopheles-producing borrow-pits close to them are common.

It is proposed to continue the "propaganda-with-treatment" campaign.

The writer advises railway administrators to consider the effect on health of man-made topographical changes near stations, to consider the future health status of employees in connection with location of sites for stations, quarters, offices, etc. He advises against the dumping camps of newly imported labor in midst of a railway colony and against drainage operations being so carried out as to increase the Anopheles output in place of decreasing it

(*Abstractor's comment.*—A survey made at Panama during the canal-construction period showed that the forces working on night shifts had a lower malaria rate than that of the dayworking forces. The writer states that in the work of the St Louis Southwestern Railway in the United States a large special staff and adequate funds were available and the campaign was designed as a cooperative measure between the railway and the adjacent municipalities During the first year of the American railway work only $3,000 was available. These funds were so used as to demonstrate to a number of municipalities that it would pay them a handsome financial return to cooperate with the efforts of the railroad The railroad was losing potential profits because of malaria prevalence. It therefore invested each dollar so as to get that dollar back several times each year forever after the work had advanced, and it accomplished its objective. While it is not known how many thousands of dollars per year the Eastern Bengal Railway is losing because of malaria prevalence, yet the abstractor (who initiated the first work done by the St. Louis Southwestern Railway and selected the worst malaria section to start the demonstration in, with a view to proving to the railroad executives that malaria control means increased railroad revenue) feels sure that properly directed malaria control, including preliminary emergency control measures not mentioned by the writer, may be as important to the Eastern Bengal Railway and many other railways in the British colonies in the Tropics as is the upkeep of track and rolling stock. It is to be hoped

that the directors and executives of more British and more American railroads will before long investigate their present unnecessary annual financial loss caused by malaria, and thus obtain that worth-while increased income which is within their reach but yet ignored by them. The total amount spent to date by the St Louis Southwestern Railway for malaria control as compared with the profits gained by increased efficiency of its employees, by increased freight handled, and increased development of its territory is a relatively small amount. Its investments in malaria control are decreasing, while its income from the territory sanitated is increasing.)

Cresol Saponified as a Larvicide. C Strickland, professor medical entomology, School Tropical Medicine and Hygiene, Calcutta, and D. N Roy, assistant professor medical entomology, in the same institution (Including a note on the cresols by Maj. A D. Stewart)' *Journal Royal Army Medical Corps*, vol 46, No 3, September, 1926, pp 188–195. (Abstract by M A Barber)

Varying dilutions of saponified cresol in water were applied to *Anopheles rossi* and to *Stegomyia* and other culicines. In a dilution of 1 in 10 by 5 all larvæ were killed in 42 hours, but in a dilution of 1 in 10 only about 15 per cent died in 24 hours. Toxicity is less marked in dilutions made in polluted river waters. *Anophelines* are more resistant to this larvicide than stegomyia and culicines, and pupæ more resistant than larvæ. Fish and shrimps were relatively much more affected than larvæ. Dilutions of saponified cresol rapidly lose their efficacy. In field trials the authors found a dilution of 1 in 50,000 the greatest of any utility, and this would represent a relatively prohibitive cost. Major Stewart's note summarized: The germicidal coefficient of a coal-tar disinfectant is no sure guide to its larvicidal value; and the proportionate amount and nature of its constituents have to be considered in gauging its larvicidal power, the hydrocarbon oils probably play a much larger part than might be thought, in comparison with the phenoloids; the comparative larvicidal power of the "phenoloid" series has apparently not been determined as has the germicidal power; the composition of the diluting water is of importance.

Larvicidal Action of Cresol. Maj. C. H. Harold, Royal Army Medical Corps. *Journal Royal Army Medical Corps*, vol. 46, No. 3, September, 1926, pp. 180–187. (Abstract by M. A. Barber.)

The larvicidal as well as the germicidal efficiency of the cresol tested is enhanced by increase of temperature; by the presence of acid, although in excess of the amounts of acid obtaining in nature; and by the presence of common salt. However, a cresol may be highly germicidal but a relatively poor larvicide. A cresol may produce torpor in a mosquito larva which may appear to be dead, but will subsequently revive, especially if left on the surface of

water or otherwise well aerated. Exposure to nonlethal solutions of cresol may increase the resistance of larvæ to solutions ordinarily lethal. The presence of organic silt lining a pool may retard the action of cresol on larvæ

The author tested the effect of cresol on the culicine *A punctor* and on *Anopheles bifurcatus*. Pupæ were more resistant than larvæ to the cresols tested and the anophelines more resistant than the culicines. A cresol tested in the presence of organic silt was effective against the culicine in a 1 in 20,000 dilution and against the anopheline in a 1 in 10,000 dilution

Design of Small Sewage Disposal Plants. F Johnstone Taylor, consulting engineer, Warrington, England. *Canadian Engineer*, vol. 51, No. 11, September 14, 1926, pp. 285–287 (Abstract by Rudolph E. Thompson.)

Description and discussion of sewage disposal systems for individual houses or institutions. Suitable designs of septic tanks and of contact beds and percolating filters for treatment of septic-tank effluents are described and illustrated. The importance of simplicity in design is emphasized.

Developments in Methods of Sewage Disposal. C. G. Gillespie, director, bureau of sanitary engineering, California State Board of Health. *Pacific Municipalities*, vol. 40, No. 8, August, 1926, pp 303–317. (Abstract by C. G. Gillespie.)

The article is a rather nontechnical review of the evolution of sewage treatment from its beginning in England about 70 years ago. A point stressed is the great need of deeper understanding of the scientific use of the lower flora and fauna in sewage treatment and the achievements of the present due to the bit of knowledge now possessed. Considerable space is devoted to the rapid development of the activated sludge method and its success and suitability to California conditions because of potential freedom from odors and the need of irrigation water which it can supply, and production of an excellent fertilizer. There are now three good-sized activated sludge plants in California: Lodi, population 8,000, uses ridge and furrow aeration with sludge dried on soil beds; Pasadena, population 100,000, ridge and furrow aeration, now buries sludge filtered on an Oliver filter, but is about to dry it by direct heat driers; Pomona, population 20,000, uses the Manchester type of aeration with anaerobic digestion of sludge in the Imhoff tank ahead of the aerators.

Report of the Bureau of Uncinariasis of the Department of Health, 1924–25. *Porto Rico Health Review*, vol. 1, No. 10, April, 1926, pp. 29–38. (Abstract by D. L. Augustine.)

The bureau of uncinariasis was created in 1923 to take charge of the increasingly important work of prevention and treatment of

uncinariasis The work of the bureau consists largely in sanitation to prevent infection and in giving treatments for the cure of the disease During the year 22,408 latrines were approved, and it is now estimated that over one-fourth of the total rural population is provided with sanitary accommodations During the year 36,239 rural inhabitants were examined, of which over 90 per cent were found infected with hookworms; 139,585 treatments were given to 38,269 persons, most of whom were freed of their parasites.

The work of the bureau is divided into three principal phases: (1) Sanitation, (2) conservation, and (3) treatment

Observations on the Development of Hookworm Larvæ. P. R. Maplestone *Annals of Tropical Medicine and Parasitology*, vol. 20, No. 2, June, 1924, pp 167–173 (Abstract by D L Augustine)

A series of experiments shows that urine has a definite effect in destroying both hookworm eggs and freshly hatched larvæ The eggs are killed in urine after 9 to 14 days. It was found that 4 days' complete immersion in water kills about 25 per cent of a given number of hookworm eggs and that a steady diminution occurs in the number of viable eggs recoverable from water as immersion is continued After a period of five weeks' immersion all the eggs appear to be dead From these observations it seems safe to conclude that septic tanks would have some effect in reducing hookworm infection, the actual reduction being directly dependent on the time the feces remained in the tank.

DEATHS DURING WEEK ENDED NOVEMBER 27, 1926

Summary of information received by telegraph from industrial insurance companies for week ended November 27, 1926, and corresponding week of 1925. (From the Weekly Health Index, December 2, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended November 27, 1926	Corresponding week, 1925
Policies in force	66, 126, 032	62, 247, 321
Number of death claims	10, 451	10, 192
Death claims per 1,000 policies in force, annual rate	8. 2	8. 5

19528°—26——3

Deaths from all causes in certain large cities of the United States during the week ended November 27, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, December 2, 1926, issued by the Bureau of the Census, Department of Commerce)

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended November 20, 1926, 41 States reported 2,702 cases of diphtheria. For the week ended November 21, 1925, the same States reported 2,298 cases of this disease. One hundred and one cities, situated in all parts of the country and having an aggregate population of more than 30,400,000, reported 1,345 cases of diphtheria for the week ended November 20, 1926. Last year for the corresponding week they reported 1,007 cases. The estimated expectancy for these cities was 1,392 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-nine States reported 4,215 cases of measles for the week ended November 20, 1926, and 3,576 cases of this disease for the week ended November 21, 1925. One hundred and one cities reported 788 cases of measles for the week this year, and 1,273 cases last year.

Poliomyelitis.—The health officers of 41 States reported 40 cases of poliomyelitis for the week ended November 20, 1926. The same States reported 70 cases for the week ended November 21, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Forty-one States—this year, 3,905 cases; last year, 3,435 cases; 101 cities—this year, 1,242 cases; last year, 1,021 cases; estimated expectancy, 942 cases.

Smallpox.—For the week ended November 20, 1926, 41 States reported 370 cases of smallpox. Last year for the corresponding week they reported 292 cases. One hundred and one cities reported smallpox for the week as follows: 1926, 28 cases; 1925, 93 cases; estimated expectancy, 47 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Six hundred and fifty-nine cases of typhoid fever were reported for the week ended November 20, 1926, by 41 States. For the corresponding week of 1925 the same States reported 627 cases of this disease. One hundred and one cities reported 92 cases of typhoid fever for the week this year and 96 cases for the corresponding week last year. The estimated expectancy for these cities was 95 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 95 cities, with a population of more than 29,730,000, as follows: 1926, 760 deaths; 1925, 865 deaths.

City reports for week ended November 20, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended November 20, 1926, compared with those for a like period ended November 21, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly

30,000,000 in 1925 and nearly 30,500,000 in 1926 The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, October 17 to November 20, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Surabaya	0	0	0	0	1	0							

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Aden, Jeddah, Kamaran, Perim.

Iraq.—Basrah

Persia.—Mohammerah, Bender-Abbas, Bushire.

British India.—Rangoon, Karachi, Chittagong, Cochin, Vizagapatam, Negapatam, Tuticorin.

Portuguese Indies.—Nova Goa

Ceylon.—Colombo

Federated Malay States.—Port Swettenham.

Straits Settlements.—Penang

Dutch East Indies.—Samarang, Batavia, Sabang, Makassar, Banjermasin, Palembang, Pontianak, Belawan-Deli, Padang, Samarinda, Balikpapan

Sarawak.—Kuching

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao

Portuguese Timor.—Dilly

China.—Amoy, Shanghai (International Settlement)

Hongkong

Macao

Formosa.—Keelung.

Japan.—Yokohama, Osaka, Nagasaki, Kobe, Niigata, Tsuruga, Hakodate, Shimonoseki, Moji

Korea.—Chemulpo

Manchuria.—Mukden, Changchun, Harbin, Antung, Yingkow.

Kwantung.—Port Arthur, Dairen.

U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.

New Guinea.—Port Moresby.

New Britain Mandated Territory.—Rabaul and Kokopo

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin

New Caledonia.—Noumea

Fiji.—Suva

Hawaii.—Honolulu

Society Islands.—Papeete

AFRICA

Egypt.—Port Said, Suez, Alexandria

Anglo-Egyptian Sudan.—Port Sudan, Suakin.

Eritrea.—Massaua

French Somaliland.—Jibuti

British Somaliland.—Berbera

Italian Somaliland.—Mogadiscio

Kenya.—Mombasa

Zanzibar.—Zanzibar

Tanganyika.—Dar-es-Salaam

Seychelles.—Victoria

Madagascar.—Majunga, Tamatave

Portuguese East Africa.—Mozambique, Beira, Lourenço Marques.

Union of South Africa.—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indies—Tarakan, Menado
Philippine Islands—Manila, Iloilo, Jolo, Cebu, Zamboanga
Union of South Africa—Durban

BRAZIL

Mortality from certain diseases—Para—September 26–October 30, 1926.—During the period September 26 to October 30, 1926, 50 deaths from gastroenteritis, 28 from malaria, and 8 from smallpox were reported at Para, Brazil. Population, 185,000

Leprosy—During the period under report leprosy was continuously reported present at Para.

CANADA

Communicable diseases—Week ended November 13, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended November 13, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever				1				1
Influenza	11					1		12
Poliomyelitis			2	4				6
Smallpox				17	25	4	9	55
Typhoid fever	3	4	9	10	1	7		34

Vital statistics—Quebec—September, 1926.—Births and deaths in the Province of Quebec for the month of September have been reported as follows:

Estimated population	2,570,000	Deaths from—Continued.	
Births	6,598	Heart disease	374
Birth rate per 1,000 population	30.80	Influenza	38
Deaths (all causes)	2,932	Measles	6
Death rate per 1,000 population	13.69	Poliomyelitis (infantile paralysis)	1
Deaths under 1 year	1,171	Scarlet fever	9
Infant mortality rate	177.47	Syphilis	6
Deaths from—		Tuberculosis (pulmonary)	189
Cancer	133	Tuberculosis (other forms)	44
Cerebrospinal meningitis	5	Typhoid fever	22
Diabetes	21	Whooping cough	47
Diphtheria	18		

CANARY ISLANDS

Plague—Las Palmas—November 2, 1926.—Three cases of plague were reported, November 2, 1926, at Las Palmas, Canary Islands. The occurrence was stated to be in a locality removed from the port.

EGYPT

Plague—October 22–28, 1926.—During the week ended October 28, 1926, a case of plague was reported in Egypt occurring in the district of Tanta.

Summary.—From January 1 to October 28, 1926, 140 cases of plague were reported in Egypt, as compared with 134 cases reported during the corresponding period of the year 1925.

ESTONIA

Communicable diseases—September, 1926.—Communicable diseases were reported in the Republic of Estonia during the month of September, 1926, as follows:

Disease	Cases	Disease	Cases
Diphtheria	19	Scarlet fever	246
Leprosy	1	Tuberculosis	123
Measles	103	Typhoid fever	93
Paratyphoid fever	25		

Population, census, 1,107,059

LATVIA

Communicable diseases—September, 1926.—During the month of September, 1926, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Diphtheria	40	Rabies	2
Dysentery	22	Scarlet fever	292
Erysipelas	18	Tetanus	2
Measles	13	Trachoma	20
Mumps	1	Typhoid fever	102
Paratyphoid fever	3	Whooping cough	46
Puerperal fever	1		

Population, 1,850,000.

Botulism.—During the same period eight cases of botulism were reported in the Republic of Latvia.

MALTA

Communicable diseases—October, 1926.—During the month of October, 1926, communicable diseases were reported in the island of Malta as follows:

Disease	Cases	Disease	Cases
Broncho-pneumonia	6	Pneumonia	5
Diphtheria	6	Puerperal infection	2
Erysipelas	2	Scarlet fever	1
Influenza	3	Trachoma	143
Lethargic encephalitis	1	Tuberculosis	17
Malaria	1	Typhoid fever	72
Malta fever	58	Whooping cough	21
Measles	19		

Population, civil, estimated, 225,242

MEXICO

Mortality from gastroenteritis—Progreso—November 14-27, 1926—Contaminated water supply.—During the two weeks ended November 27, 1926, eight deaths from gastroenteritis were reported at Progreso, Mexico. Population, 9,089. Contamination of cisterns and other water supplies was reported.

PERU

Communicable diseases—Lima—August, 1926.—During the month of August, 1926, communicable diseases were reported in the city of Lima, Peru, as follows:

Disease	Cases	Disease	Cases
Gastroenteritis	27	Puerperal septicemia	1
Influenza	10	Tuberculosis	73
Malaria	11	Typhoid fever	3
Plague	1		

Population, 210,000.

UNION OF SOUTH AFRICA

Plague—Cape Province—October 10-16, 1926.—During the week ended October 16, 1926, two fatal cases of plague were reported in the Cape Province, Union of South Africa, of which one (native or colored) occurred in Hanover District and one (European) in Kimberley District. Both cases occurred on farms

Smallpox.—Outbreaks of smallpox were reported during the period under report as follows: In the Umgeni area, Durban, 12 cases, of which 11 cases were Hindus and 1 case native; at Prospect Hall, Inanda District, 1 case, native, in a contact with the Durban cases. The cases were removed to Salisbury Island quarantine, Durban Bay.

YUGOSLAVIA

Communicable diseases—September, 1926.—During the month of September, 1926, communicable diseases were reported in Yugoslavia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	89	10	Scarlet fever	470	75
Meningococcus meningitis	3	2	Tetanus	32	18
Diphtheria	180	38	Typhoid fever	586	52
Dysentery	264	24	Whooping cough	195	12
Measles	205	3			

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

The reports contained in the following tables must not be considered as complete or final as regards either the lists of countries included or the figures for the particular countries for which reports are given.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C. PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 DECEMBER 17, 1926 NO. 51

THE CONTROL OF COMMUNICABLE DISEASES

REPORT OF THE AMERICAN PUBLIC HEALTH ASSOCIATION COMMITTEE ON STANDARD REGULATIONS, APPOINTED IN OCTOBER, 1916

In the following report the terms used are first defined. Each disease is briefly described with regard to the infective agent, the source of infection, the mode of transmission, the incubation period, and the period of communicability Following this are given the methods of control—first, those affecting the individual patient and his immediate environment, and, second, general measures bearing upon the control or prevention of the disease in question.

Inasmuch as the laws under which various boards and departments of health operate require differences in the legal phraseology of rules, regulations, or sections of sanitary codes dealing with the control of communicable diseases, the committee has refrained from preparing formal regulations under each disease. As the report is at present submitted any health officer, board of health, or legislative body having the power to make rules or regulations or pass sections of sanitary codes dealing with the control of communicable diseases can, by reference to the description of the disease and recommendations for methods of control herewith proposed, easily prepare the necessary text upon which the educational and administrative acts of the health officer will be based.

The committee is indebted for expert opinion and critical comment upon its tentative conclusions to Dr. Simon Flexner, Dr. William H. Park, Prof. Theobald Smith, and Dr. Bertram H. Waters, and acknowledgment of their contributions to the report in its present form is herewith gratefully expressed.

HAVEN EMERSON, M. D., *Chairman.*
ROBERT N. HOYT.
F. M. MEADER, M. D.
J. C. PERRY, M. D.
C.-E. A. WINSLOW, Dr P. H.

This revised report of the committee on control of communicable diseases was presented before the public health administration section at the fifty-fifth annual meeting of the American Public Health Association at Buffalo, N. Y., on October 11, 1926. Publication of the revised report was approved by the governing council of the association on October 14, 1926.

The committee acknowledges gratefully the collaboration of the following physicians who generously contributed to the present revised text: Doctors Charles V. Chapin, Edwin O. Jordan, William H. Park, J F. Anderson, E C. Levy, E. S. Godfrey, and certain medical officers of the Public Health Service.

HAVEN EMERSON, M. D., *Chairman.*
F. E. HARRINGTON, M. D.
ALLAN J. MCLAUGHLIN, M. D.
M. M. SEYMOUR, M. D.
C.-E. A. WINSLOW, Dr. P. H.

This revised report of the committee on control of communicable diseases is officially approved by the United States Public Health Service.

List of Diseases

Actinomycosis.
Acute infectious conjunctivitis.
Anchylostomiasis (hookworm).
Anthrax.
Chicken pox.
Cholera.
Dengue.
Diphtheria.
Dysentery (amoebic).
Dysentery (bacillary).
Epidemic (lethargic) encephalitis.
Favus.
German measles.
Glanders.
Gonorrhea.
Influenza.
Leprosy.
Malaria.
Malta fever.
Measles.
Meningococcus meningitis.
Mumps
Paratyphoid fever.
Plague.
Pneumonia (acute lobar).
Poliomyelitis
Rabies
Rocky Mountain spotted or tick fever.
Scarlet fever.
Septic sore throat.
Smallpox.
Syphilis
Tetanus.
Trachoma
Trichinosis
Tuberculosis (pulmonary).
Tuberculosis (other than pulmonary).
Tularæmia.
Typhoid fever
Typhus fever.
Whooping cough.
Yellow fever.

The committee adopted the following definitions of terms:

1. *Carrier*.—A person who, without symptoms of a communicable disease, harbors and disseminates the specific microorganisms.

2. *Cleaning*.—This term signifies the removal by scrubbing and washing, as with hot water, soap, and washing soda, of organic matter on which and in which bacteria may find favorable conditions for prolonging life and virulence; also the removal by the same means of bacteria adherent to surfaces.

3. *Contact*.—A "contact" is any person or animal known to have been sufficiently near to an infected person or animal to have been presumably exposed to transfer of infectious material directly, or by articles freshly soiled with such material.

4. *Delousing*.—By delousing is meant the process by which a person and his personal apparel are treated so that neither the adults nor the eggs of Pediculus corporis or Pediculus capitis survive.

5. *Disinfection*.—By this is meant the destroying of the vitality of pathogenic microorganisms by chemical or physical means.

When the word *concurrent* is used as qualifying disinfection, it indicates the application of disinfection immediately after the discharge of infectious material from the body of an infected person, or after the soiling of articles with such infectious discharges, all personal contacts with such discharges or articles being prevented prior to their disinfection.

When the word *terminal* is used as qualifying disinfection, it indicates the process of rendering the personal clothing and immediate physical environment of the patient free from the possibility of conveying the infection to others, at the time when the patient is no longer a source of infection.

6. *Disinfesting*.—By disinfesting is meant any process, such as the use of dry or moist heat, gaseous agents, poisoned food, trapping, etc., by which insects and animals known to be capable of conveying or transmitting infection may be destroyed.

7. *Education in personal cleanliness*.—This phrase is intended to include all the various means available to impress upon all members of the community, young and old, and especially when communicable disease is prevalent or during epidemics, by spoken and printed word, and by illustration and suggestion, the necessity of

(1) Keeping the body clean by sufficiently frequent soap and water baths.

(2) Washing hands in soap and water after voiding bowels or bladder and always before eating.

(3) Keeping hands and unclean articles, or articles which have been used for toilet purposes by others, away from mouth, nose, eyes, ears, and vagina.

(4) Avoiding the use of common or unclean eating, drinking, or toilet articles of any kind, such as towels, handkerchiefs, hair brushes, drinking cups, pipes, etc.

(5) Avoiding close exposure of persons to spray from the nose and mouth, as in coughing, sneezing, laughing, or talking.

8. *Fumigation*.—By fumigation is meant a process by which the destruction of insects, as mosquitoes and body lice, and animals, as rats, is accomplished by the employment of gaseous agents.

9. *Isolation*.[1]—By isolation is meant the separating of persons suffering from a communicable disease, or carriers of the infecting organism, from other persons, in such places and under such conditions as will prevent the direct or indirect conveyance of the infectious agent to susceptible persons.

10. *Quarantine*.[1]—By quarantine is meant the limitation of freedom of movement of persons or animals who have been exposed to communicable disease for a period of time equal to the longest usual incubation period of the disease to which they have been exposed.

11. *Renovation*.—By renovation is meant, in addition to cleansing, such treatment of the walls, floors, and ceilings of rooms or houses as may be necessary to place the premises in a satisfactory sanitary condition.

12. *Report of a disease*.—By report of a disease is meant the notification to the health authorities, and, in the case of communicable disease in animals, also to the respective departments of agriculture which have immediate jurisdiction, that a case of communicable disease exists in a specified person or animal at a given address.

---

[1] In view of the various ambiguous and inaccurate uses to which the words isolation and quarantine are not infrequently put, it has seemed best to adopt arbitrarily the word isolation as describing the limitation put upon the movements of the known sick or "carrier" individual or animal, and the word quarantine as describing the limitations put upon exposed or "contact" individuals.

13. *Susceptibles* —A susceptible is a person or animal who is not known to have become immune to the particular communicable disease in question by natural or artificial process

The items considered necessary for presentation by the committee with regard to each disease are the following:

1. Infective agent.
2. Source of infection
3. Mode of transmission
4. Incubation period.
5. Period of communicability.
6. Methods of control
   (A) The infected individual and his environment:
      1 Recognition of the disease.
      2 Isolation.
      3 Immunization
      4. Quarantine.
      5. Concurrent disinfection.
      6. Terminal disinfection
   (B) General measures.
   (C) Epidemic measures (occasionally require separate mention).

IMPORTANT MEASURES IN BOLD-FACED TYPE

Certain measures in the control of some diseases are of particular importance, on account either of their efficiency in preventing the disease or of the danger if they are neglected, and also on account of their proven practicability. These are emphasized in the text by **being printed in bold-faced type.**

Actinomycosis

1. *Infective agent.*—*Actinomyces bovis*
2. *Source of infection* —The nasal and bowel discharges, and the infected material from lesions in human and animal cases of the disease Uncooked meat from infected animals may serve as a source of infection.
3. *Mode of transmission.*—By contact with the discharges or with articles freshly soiled with the discharges from animal or human cases.
4. *Incubation period.*—Unknown.
5. *Period of communicability.*—As long as open lesions remain, as proved by the presence of the infective agent on microscopic or cultural tests.
6. *Methods of control.*
   (A) The infected individual and his environment—
      1. **Recognition of the disease**—Clinical symptoms, confirmed by microscopic examination of discharges from the lesions.
      2. Isolation—None, provided the patient is under adequate medical supervision
      3. Immunization.—None.
      4 Quarantine.—None.
      5. Concurrent disinfection.—Of discharges from lesions and articles soiled therewith.
      6. Terminal disinfection.—By thorough cleaning.
   (B) General measures—
      1. **Inspection of meat, with condemnation of carcasses, or infected parts of carcasses, of infected animals.**
      2. **Destruction of known animal sources of infection.**

Acute Infectious Conjunctivitis

(Not including trachoma)

(This title to replace the terms gonorrheal ophthalmia, ophthalmia neonatorum, and babies' sore eyes)

1. *Infectious agent* —The gonococcus or some member of a group of pyogenic organisms, including the hemoglobinophilic bacilli
2. *Source of infection* —Discharges from conjunctivæ, or adnexa, or genital mucous membranes of infected persons.
3. *Mode of transmission* —Contact with an infected person or with articles freshly soiled with discharges of such person
4. *Incubation period.*—Irregular, but usually 36 to 48 hours.
5. *Period of communicability.*—During the course of the disease and until the discharges from the infected mucous membranes have ceased.
6. *Methods of control*·
   - (A) The infected individual and his environment—
     1. Recognition of the diseases—Clinical symptoms, confirmed where possible by bacteriological examination
     2. Isolation—None, provided the patient is under adequate medical supervision.
     3. Immunization—None
     4. Quarantine—None
     5. **Concurrent disinfection—Disinfection of conjunctival discharges and articles soiled therewith.**
     6. Terminal disinfection—Thorough cleansing
   - (B) General measures—
     1. Enforcement of regulations forbidding the use of common towels and toilet articles Education as to personal cleanliness.
     2. **Use of silver nitrate or some similar solution in the eyes of the new born.**
     3. Carrying out of the measures indicated on methods of control for gonorrhea.

Anchylostomiasis

(Hookworm)

1. *Infectious agent.*—Anchylostoma (*Necator americanus*).
2. *Source of infection.*—Feces of infected persons Infection generally takes place through the skin, occasionally by the mouth.
3. *Mode of transmission* —The larval forms pierce the skin, usually of the foot, and passing through the lymphatics to the vena cava and the right heart, thence in the blood stream to the lungs, they pierce the capillary walls and pass into the alveoli Then they pass up the bronchi and trachea to the throat, whence they are swallowed and finally lodge in the small intestine. Also by drinking water containing larvæ, by eating soiled food, by hand to mouth transmission of the eggs or larvæ from objects soiled with infected discharges. The chief reservoir of infectious material is *contaminated soil.*
4. *Incubation period.*—Seven to ten weeks
5. *Period of communicability.*—As long as the parasite or its ova are found in the bowel discharges of an infected individual. Contaminated soil remains infective for five months in the absence of freezing.

6. *Methods of control:*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Microscopic examination of bowel discharges
      2 Isolation—None
      3. Immunization—None.
      4 Quarantine—None.
      5 Concurrent disinfection—Sanitary disposal of bowel discharges to prevent contamination of soil and water.
      6. Terminal disinfection—None
      7 Treatment—Appropriate treatment of infected individual to rid the intestinal canal of the parasite and its ova.
   (B) General measures—
      1. Education as to dangers of soil pollution
      2. Prevention of soil pollution by installation of sanitary disposal systems for human discharges
      3. Personal prophylaxis by cleanliness and the wearing of shoes.

Anthrax

1. *Infectious agent*.—Anthrax bacillus, *Bacillus anthracis*.
2. *Source of infection*.—Hair, hides, flesh, and feces of infected animals
3. *Mode of transmission*.—Inoculation as by accidental wound or scratch, inhalation of spores of the infectious agent, and ingestion of insufficiently cooked infected meat.
4. *Incubation period*.—Within seven days.
5. *Period of communicability*.—During the febrile stage of the disease and until lesions have ceased discharging. Infected hair and hides of infected animals may communicate the disease for many months after slaughter of the animal, and after curing of hide, fur, or hair, unless disinfected.
6. *Methods of control:*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, confirmed by bacteriological examination.
      2. Isolation of the infected individual until the lesions have healed.
      3. Immunization—None.
      4. Quarantine—None.
      5. Concurrent disinfection of the discharges from lesions and articles soiled therewith
      6. Terminal disinfection—Thorough cleaning.
   (B) General measures—
      1. Animals ill with a disease presumably anthrax should be placed immediately in the care of a veterinary surgeon. Proved animal cases of the disease should be killed promptly and the carcasses destroyed, preferably by fire.
      2. Isolation of all animals affected with the disease.
      3. Immunization of exposed animals under direction of Federal or State Department of Agriculture.
      4. Post-mortem examinations should be made only by a veterinary surgeon, or in the presence of one.
      5. Milk from an infected animal should not be used during the febrile period.

6. *Methods of control*—Continued.

(B) General measures—Continued.

6. Control and disinfection of effluents and trade wastes and of areas of land polluted by such effluents and wastes from factories or premises, where spore-infected hides or other infected hide and hair products are known to have been worked up into manufactured articles.
7. A physician should be constantly employed by every company handling rawhides, or such companies should operate under the direct supervision of a medical representative of the health department
8. Every employee handling rawhides, hair, or bristles who has an abrasion of the skin should immediately report to a physician.
9. Special instruction should be given to all employees handling rawhides in regard to the necessity of personal cleanliness.
10. Tanneries and woolen mills should be provided with proper ventilating apparatus so that dust can be promptly removed
11. Disinfection of hair, wool, and bristles of animals originating in known infected centers before they are used or assorted
12. The sale of hides from an animal infected with anthrax should be prohibited. A violation of this regulation should be immediately reported to the State commissioner of agriculture, by telegram, stating the time, place, and purchaser to whom the hide was sold The report should also be sent to the person purchasing the hide Carcasses should be disposed of under the supervision of the State department of agriculture. The inspection and disinfection of imported hides are under the supervision of the United States Bureau of Animal Industry. In the event that infection is introduced the State agricultural authorities have jurisdiction over infected animals and the local or State health authorities have jurisdiction over infected persons.

Chicken Pox

1. *Infectious agent.*—Unknown.
2. *Source of infection.*—The infectious agent is presumably present in the lesions of the skin and of the mucous membranes; the latter appearing early and rupturing as soon as they appear, render the disease communicable early, that is, before the exanthem is in evidence.
3. *Mode of transmission.*—Directly from person to person; indirectly through articles freshly soiled by discharges from an infected individual.
4. *Incubation period.*—Two to three weeks.
5. *Period of communicability.*—Until the primary scabs have disappeared from the mucous membranes and the skin
6. *Methods of control:*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms. **The chief public health importance of this disease is that cases thought to be chicken pox in persons over 15 years of age, or at any age during an epidemic of smallpox, are to be investigated to eliminate the possibility of their being smallpox.**
2. Isolation—Exclusion of patient from school, and prevention of contact with nonimmune persons.
3. Immunization—None.

Methods of control—Continued

(A) The infected individual and his environment—Continued.

4. Quarantine—None

5. Concurrent disinfection of articles soiled by discharges from lesions

6 Terminal disinfection—Thorough cleaning.

(B) General measures—None.

Cholera

1. *Infectious agent*—Cholera vibrio, *Vibrio comma.*
2. *Source of infection.*—Bowel discharges and vomitus of infected persons, and feces of convalescent or healthy carriers. Ten per cent of contacts may be found to be carriers.
3. *Mode of transmission*—By food and water polluted by infectious agent; by contact with infected persons, carriers, or articles freshly soiled by their discharges, by flies
4. *Incubation period*—One to five, usually three days, occasionally longer if the healthy carrier stage, before development of symptoms, is included.
5. *Period of communicability.*—Usually 7 to 14 days or longer and until the infectious organism is absent from the bowel discharges.
6. *Methods of control:*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms, confirmed by bacteriological examination.
2. Isolation of patient in hospital or screened room
3. Immunization by vaccination may be of value
4. Quarantine—Contacts for five days from last exposure, or longer if stools are found to contain the cholera vibrio.
5. Concurrent disinfection—Prompt and thorough disinfection of the stools and vomited matter. Articles used by and in connection with the patient must be disinfected before removal from the room. Food left by the patient should be burned
6 Terminal disinfection—Bodies of those dying from cholera should be cremated if practicable, or, otherwise, wrapped in a sheet wet with disinfectant solution and placed in water-tight caskets. The room in which a sick patient was isolated should be thoroughly cleaned and disinfected

(B) General measures—

1. Rigid personal prophylaxis of attendants by scrupulous cleanliness, disinfection of hands each time after handling patient or touching articles contaminated by dejecta, the avoidance of eating or drinking anything in the room of the patient, and the prohibition of those attendant on the sick from entering the kitchen
2. The bacteriological examination of the stools of all contacts to determine carriers Isolation of carriers.
3. Water should be boiled, if used for drinking or toilet purposes, or if used in washing dishes or food containers, unless the water supply is adequately protected against contamination or is so treated, as by chlorination, that the cholera vibrio can not survive in it.

6. *Methods of control*—Continued.
   (B) General measures—Continued.
      4. **Careful supervision of food and drink. Where cholera is prevalent, only cooked foods should be used. Food and drink after cooking or boiling should be protected against contamination, as by flies and human handling.**
   (C) Epidemic measures—
      Inspection service for early detection and isolation of cases; examination of persons exposed in infected centers for detection of carriers, with isolation or control of carriers; disinfection of rooms occupied by the sick, and the detention, in suitable camps for five days, of those desirous of leaving for another locality. Those so detained should be examined for detection of carriers.

Dengue

1. *Infectious agent*.—Unknown.
2. *Source of infection*.—The blood of infected persons.
3. *Mode of transmission*.—By the bite of infected mosquitoes, *Aedes ægypti*.
4. *Incubation period*.—Three to ten days.
5. *Period of communicability*.—From the day before onset to the fifth day of the disease.
6. *Methods of control*.
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms.
      2. Isolation—The patient must be kept in a screened room.
      3. Immunization—None.
      4. Quarantine—None.
      5. Concurrent disinfection—None.
      6. Terminal disinfection—None. Upon termination of the case, fumigation of the room and house, to destroy mosquitoes.
   (B) General measures—
      Measures directed toward elimination of mosquitoes (Aedes ægypti). Screening of rooms.

Diphtheria

1. *Infectious agent*.—Diphtheria bacillus, *Corynebacterium diphtheriæ*, the Klebs-Loeffler bacillus.
2. *Source of infection*.—Discharges from diphtheritic lesions of nose, throat, conjunctiva, vagina, and wound surfaces. Secretions from the nose and throat of carriers of the bacillus.
3. *Mode of transmission*.—Directly by personal contact, indirectly by articles freshly soiled with discharges, or through infected milk or milk products.
4. *Incubation period*.—Usually two to five days, occasionally longer if a healthy carrier stage precedes the development of clinical symptoms.
5. *Period of communicability*.—Until virulent bacilli have disappeared from the secretions and the lesions. The persistence of the bacilli after the lesions have healed is variable. In fully three-fourths of the cases they disappear within two weeks. In 95 per cent of cases, the bacilli disappear in four weeks. In exceptional cases virulent bacilli remain in the throat and discharges for from two to six months.

6. *Methods of control.*

(A) The infected individual and his environment—

1 Recognition of the disease—By clinical symptoms with confirmation by bacteriological examination of discharges.

2 Isolation—Until two cultures from the throat and two from the nose, taken not less than 24 hours apart, fail to show the presence of diphtheria bacilli. Isolation may be terminated if persistent diphtheria bacilli prove avirulent. Where termination by culture is impracticable, cases may be terminated with fair safety as a rule 16 days after onset of the disease.

3. Immunization—Exposed susceptibles who can not be kept under daily observation by a physician or nurse should be promptly immunized by antitoxin. (By susceptibles is meant such individuals as are found to be nonimmune by the Schick test, i. e , those who give a positive reaction.)

4. Quarantine—All exposed persons until shown by bacteriological examination not to be carriers.

5. Concurrent disinfection of all articles which have been in contact with the patient and all articles soiled by discharges from the patient.

6. Terminal disinfection—At the end of the illness, thorough airing and sunning of the sick room, with cleaning or renovation.

(B) General measures—

1. Pasteurization of milk supply.

2. Application of the Schick test to all especially exposed persons, such as nurses and physicians, and active immunization of all susceptibles, but not within three weeks after the administration of antitoxin.

3 Active immunization of all children by the end of the first year without prior Schick testing, active immunization of school children with or without prior use of the Schick test.

4. Determination of presence or absence of carriers among contacts and, so far as practicable, in the community at large.

Dysentery (Amœbic)

1. *Infectious agents.—Endamœba histolytica.*

2. *Source of infection.*—The bowel discharges of infected persons.

3. *Mode of transmission* —By drinking contaminated water, and by eating infected foods, and by hand-to-mouth transfer of infected material; from objects soiled with discharges of an infected individual, or of a carrier; by flies

4. *Incubation period.*—Unknown

5. *Period of communicability.*—During course of disease and until repeated microscopic examination of stools shows absence of Amœba histolytica.

6. *Methods of control.*—

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms, confirmed by microscopic examination of stools.

2. Isolation—None

3. Immunization—None.

4. Quarantine—None.

5. Concurrent disinfection of the bowel discharges.

6. Terminal disinfection—Cleaning.

6. *Methods of control*—Continued.
   (B) General measures—
      1. Boil drinking water unless the supply is known to be free from contamination.
      2. Water supply should be protected against contamination, and supervision should be exercised over all foods eaten raw.

Dysentery (Bacillary)

1. *Infectious agent.*—Dysentery bacillus, *Eberthella dysenteriæ, Eberthella para dysenteriæ.*
2. *Source of infection.*—The bowel discharges of infected persons.
3. *Mode of transmission.*—By drinking contaminated water, by eating infected foods, and by hand-to-mouth transfer of infected material; from objects soiled with discharges of an infected individual or of a carrier, by flies.
4. *Incubation period.*—Two to seven days.
5. *Period of communicability.*—During the febrile period of the disease and until the organism is absent from the bowel discharges.
6. *Methods of control.*—
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, confirmed by serological and bacteriological tests.
      2. Isolation—Infected individuals during the communicable period of the disease.
      3. Immunization—Vaccines give considerable immunity. Owing to severe reactions their use is not universal, nor should it be made compulsory except under extreme emergency.
      4. Quarantine—None.
      5. Concurrent disinfection—Bowel discharges.
      6. Terminal disinfection—Cleaning.
   (B) General measures—
      1. Rigid personal prophylaxis of attendants upon infected persons.
      2. No milk or food for human consumption should be sold from a place occupied by a patient unless the persons engaged therein occupy quarters separate from the house where the patient is sick, and all utensils used are cleaned and kept in a separate building and under a permit from the health officer.
      3. All attendants upon persons affected with this disease should be prohibited from having anything to do with the handling of food.
      4. Necessary precautions against flies.
      5. Careful supervision of food and drink. Where dysentery is prevalent, only cooked foods should be used. Food and drink after cooking or boiling should be protected against contamination, as by flies and human handling.

Epidemic (Lethargic) Encephalitis

1. *Infectious agent.*—Unknown.
2. *Source of infection.*—Probably discharges from the nose and throat of infected persons, or articles freshly soiled therewith. It is supposed that there are healthy carriers during prevalence of the disease.
3. *Mode of transmission.*—Probably by direct contact with an infected person or a carrier of the virus, or by contact with articles freshly soiled with the discharges of the nose or throat of such persons.

4 *Incubation period*—Undetermined Believed to be about 10 days.
5 *Period of communicability*—Probably during the febrile stage of the disease.
6 *Methods of control*—
(A) The infected individual and his environment—
1 Recognition of the disease, by clinical symptoms
2 Isolation of recognized cases for one week after onset.
3 Immunization—None.
4 Quarantine—None.
5. Concurrent disinfection—Discharges of the nose and throat and articles soiled therewith.
6 Terminal disinfection—Cleaning
(B) General measures—
1. Search for and examination of cases during periods of prevalence.
2 Isolation of suspected febrile cases pending diagnosis.

Favus

1 *Infectious agent.*—*Achorion schoenleinii.*
2. *Source of infection.*—Lesions of skin, particularly on scalp.
3. *Mode of transmission.*—Direct contact with patient, and indirectly through toilet articles.
4. *Incubation period.*—Unknown.
5. *Period of communicability.*—Until skin and scalp lesions are all healed
6. *Methods of control:*
(A) The infected individual and his environment—
1. Recognition of the disease—Clinical symptoms confirmed by microscopic examination of crusts.
2 Isolation—Exclusion of patient from school and other public places until lesions are healed.
3. Immunization—None.
4. Quarantine—None.
5. Concurrent disinfection—Toilet articles of patient.
6. Terminal disinfection—None.
(B) General measures—
1. Elimination of common utensils, such as hair brushes and combs.
2. Provision for adequate and intensive treatment and cure of cases of favus at hospitals and dispensaries, to abbreviate the period of infectivity of the patients.

German Measles (Rubella)

1. *Infectious agent.*—Unknown
2. *Source of infection*—Secretions of the mouth and possibly of the nose.
3. *Mode of transmission.*—By direct contact with the patient or with articles freshly soiled with the discharges from the nose or throat of the patient.
4. *Incubation period.*—From 14 to 21 days.
5. *Period of communicability.*—Eight days from onset of the disease.
6. *Methods of control*·
(A) The infected individual and his environment—
1. Recognition of the disease—Clinical symptoms.
2. Isolation—Separation of the patient from nonimmune children, and exclusion of the patient from school and public places for the period of presumed infectivity.
3. Immunization—None.
4. Quarantine—None.

6. *Methods of control*—Continued.

(A) The infected individual and his environment—Continued.

5. Concurrent disinfection—Discharges from the nose and throat of the patient and articles soiled by discharges.

6. Terminal disinfection—Airing and cleaning

(B) General measures—None.

NOTE —The reason for attempting to control this disease is that it may be confused with scarlet fever during its early stages, each person having symptoms of the disease should therefore be placed under the care of a physician and the case should be reported to the local department of health

Glanders

1. *Infectious agent*—Glanders bacillus, *Pfefferella mallei*.
2. *Source of infection*.—Discharges from open lesions of mucous membranes or of the skin of human or equine cases of the disease i e, pus and mucus from the nose, throat, and bowel discharges from infected man and horse
3. *Mode of transmission*—Contact with a case or with articles freshly soiled by discharges from a human or equine case.
4. *Incubation period*.—Unknown.
5. *Period of communicability*—Until bacilli disappear from discharges or until lesions have healed
6. *Methods of control*

(A) The infected individual and his environment—

1. Recognition of the disease—By specific biological reactions, such as the complement fixation test, the mallein test, the agglutination test, or by nonspecific reactions, such as the Straus reaction, if confirmed by culture, or by identification of the *Bacillus mallei*, or by autopsy of doubtful cases
2. Isolation—Human case at home or hospital; for infected horses destruction rather than isolation is advised Skin contact with the lesions in the living or dead body is to be scrupulously avoided.
3. Immunization—None of established value or generally accepted.
4. Quarantine of all horses in an infected stable until all have been tested by specific reaction, and the removal of infected horses and terminal disinfection of stable have been accomplished.
5. Concurrent disinfection—Discharges from human cases and articles soiled therewith.
6. Terminal disinfection—Stables and contents where infected horses are found.

(B) General measures—

1. The abolition of the common drinking trough for horses.
2. Sanitary supervision of stables and blacksmith shops
3. Semiannual testing of all horses by a specific reaction where the disease is common.
4. Testing of all horses offered for sale where the disease is common.

NOTE —In this disease, as in all infectious or communicable diseases from which both animals and humans suffer, cases occurring in animals should be reported to the Department of Agriculture and human cases should be reported to the Department of Health, reciprocal notification thereafter to be accomplished through official interdepartment channels.

Gonorrhea

1. *Infectious agent*.—Gonococcus, *Neisseria gonorrhœæ*.
2. *Source of infection*—Discharges from lesions of inflamed mucous membranes and glands of infected persons, viz, urethral, vaginal, cervical, conjunctival mucous membranes, and Bartholin's or Skene's glands in the female, and Cowper's and the prostate glands in the male.

3. *Mode of transmission.*—By direct personal contact with infected persons, and indirectly by contact with articles freshly soiled with the discharges of such persons.
4. *Incubation period.*—One to eight days, usually three to five days
5. *Period of communicability*—As long as the gonococcus persists in any of the discharges, whether the infection be an old or a recent one.
6. *Methods of control.*
   - (A) The infected individual and his environment—
     1. Recognition of the disease—Clinical symptoms, confirmed by bacteriological examination or serum reaction.
     2. Isolation—When the lesions are in the genito-urinary tract, exclusion from sexual contact, and when the lesions are conjunctival, exclusion from school or contact with children, as long as the discharges contain the infecting organism.
     3. Immunization—None.
     4. Quarantine—None
     5. Concurrent disinfection—Discharges from lesions and articles soiled therewith.
     6. Terminal disinfection—None.
   - (B) General measures—
     1. Education in matters of sexual hygiene, particularly as to the fact that continence in both sexes at all ages is compatible with health and normal development.
     2. Provision for accurate and early diagnosis, and treatment in hospitals and dispensaries of infected persons, with consideration for privacy of record and provision for following cases until cured.
     3. Repression of prostitution by use of police power and control of use of living premises
     4. Restriction of sale of alcoholic beverages.
     5. Restrictions of advertising of services or medicines for the treatment of sex diseases, etc
     6. Elimination of common towels and toilet articles from public places.
     7. Use of prophylactic silver solution in the eyes of the new b[illegible]n.
     8. Exclusion of persons in the communicable stage of the disease from participation in the preparing and serving of food
     9. Personal prophylaxis should be advised to those who expose themselves to opportunity for infection.

Influenza

1. *Infectious agent*—Undetermined.
2. *Source of infection.*—Probably discharges from the mouth and nose of infected persons and articles freshly soiled with such discharges.
3. *Mode of transmission.*—Believed to be by direct contact, by droplet infection or by articles freshly soiled with discharges of the nose and throat of infected persons.
4. *Incubation period.*—Short, usually 24 to 72 hours.
5. *Period of communicability.*—Undetermined, apparently during the febrile period or at least for seven days from onset of clinical symptoms.

6. *Methods of control:*
   (A) The infected individual and his environment—
   1. Recognition of the disease—By clinical symptoms only. Uncertain in inter-epidemic periods
   2. Isolation—During acute stage of disease.
   3. Immunization—None; vaccines have not proved of definite value.
   4. Quarantine—None.
   5. Concurrent disinfection—Discharges from the nose and throat of the patient.
   6. Terminal disinfection—Airing and cleaning
   (B) General measures—
   During epidemics efforts should be made to reduce opportunities for direct-contact infection, as in crowded halls, stores, and street cars. Kissing, the use of common towels, glasses, eating utensils, or toilet articles should be avoided The hands should be washed carefully before eating In isolated towns and institutions, infection has been delayed and sometimes avoided by strict exclusion of visitors from already infected communities The closing of schools has not been effective in checking the spread of infection The use of masks by nurses and other attendants has proved of value in preventing infection in hospitals Scrupulous cleanliness of dishes and utensils used in preparing and serving food in public eating places should be required, including the subjection of all such articles to disinfection in hot soapsuds In groups which can be brought under daily professional inspection, the isolation of early and suspicious cases of respiratory tract inflammation, particularly when accompanied with a rise in temperature, may be relied upon to delay the spread of the disease To minimize the severity of the disease and to reduce mortality, patients should go to bed at the beginning of an attack and not return to work without the approval of their physician

Leprosy

1. *Infectious agent.*—Leprosy bacillus, ***Mycobacterium lepræ.***
2. *Source of infection.*—Discharges from lesions.
3. *Mode of transmission.*—By close, intimate, and prolonged contact with infected individuals. Flies and other insects may be mechanical carriers.
4. *Incubation period.*—Prolonged, undetermined.
5. *Period of communicability.*—Infectivity exists throughout the duration of the disease.

   Where good standards of personal hygiene prevail, this disease is but slightly communicable.
6. *Methods of control:*
   (A) The infected individual and his environment—
   1. Recognition of the disease—Clinical symptoms, confirmed by bacteriological examination.
   2. Isolation for life in national leprosarium when this is possible, or at least until treatment has brought about a healing of all lesions of skin and mucous membranes and the patient has been observed with the disease in this arrested form for not less than six months.
   3. Immunization—None.
   4. Quarantine—None.

6. *Methods of control*—Continued.
   (A) The infected individual and his environment—Continued.
      5. Concurrent disinfection—Discharges and articles soiled with discharges.
      6. Terminal disinfection—Thorough cleansing of living premises of the patient.
   (B) General measures—
      1. Lack of information as to the determining factors in the spread and communication of the disease makes any but general advice in matters of personal hygiene of no value
      2. As a temporary expedient lepers may be properly cared for in local hospitals, or if conditions of the patient and his environment warrant, he may be allowed to remain on his own premises under suitable regulations

Malaria

1. *Infectious agent.*—The several species of malarial organisms—*Plasmodium vivax* (tertian); *Plasmodium malariæ* (quartan); *Laverania falciparum* (æstivo-autumnal).
2. *Source of infection* —The blood of an infected individual.
3. *Mode of transmission.*—By bite of the infected Anopheles mosquitoes The mosquito is infected by biting an individual suffering from acute or chronic malaria. The parasite develops in the body of the mosquito for from 10 to 14 days, after which time the sporozoites appear in its salivary glands.
4. *Incubation period.*—Varies with the type of species of infecting organism and the amount of infection; usually 14 days in the tertian variety.
5. *Period of communicability* —As long as the malaria organism exists in the blood.
6. *Methods of control*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, always to be confirmed by microscopical examination of the blood Repeated examinations may be necessary.
      2. Isolation—None except protection of the patient from approach of mosquitoes by screening his bed or room or house, until his blood is rendered free from malarial parasites by thorough treatment with quinine.
      3. Immunization—None. The administration of prophylactic doses of quinine should be insisted upon for those constantly exposed to infection and unable to protect themselves against Anopheles mosquitoes.
      4. Quarantine—None
      5. Concurrent disinfection—None. Destruction of Anopheles mosquitoes in the sick room.
      6. Terminal disinfection—None. Destruction of Anopheles mosquitoes in the sick room.
   (B) General measures—
      1. Employment of known measures for destroying larvæ of anophelines and the eradication of breeding places of such mosquitoes.
      2. Blood examination of persons living in infected centers to determine the incidence of infection.
      3. Screening sleeping and living quarters; use of mosquito nets.
      4. Killing mosquitoes in living quarters.

Malta Fever

1 *Infective organism*—*Micrococcus melitensis; Brucella melitensis, Alkaligenes melitensis, Alkaligenes abortus*

2 *Source of infection*—The milk and urine of infected goats, and the urine, blood, and milk of other infected domestic animals, mules, asses, horses, cows, oxen, hogs, sheep, rabbits, dogs, and fowls; the urine of infected persons and of carriers of the organism

3 *Mode of transmission*—By ingestion of milk from infected goats commonly; by direct contact with infected animals and persons and their urinary discharges in ways to permit the contamination of food and hands, occasionally; by inhalation of dust from soil or surfaces contaminated with urinary discharges of infected animals or persons rarely; possibly by inoculation through abrasions of the skin by contaminated dust or soil, and by sexual intercourse with infected persons, and rarely by ingestion of infected cow's milk or by contact with infected blood or organs of domestic animals

4. *Incubation period*—Six to sixteen days

5 *Period of communicability*—From the onset of the disease until the organism is no longer found in the urine, usually 90 days, with a range of 20 to 300 days

6. *Methods of control.*

(A) The infected individual and his environment—

1 Recognition of the disease—The clinical picture and particularly the undulant character of the fever, supplemented by exact determination through the use of agglutination tests and bacteriological examination of the blood and urine for the infecting organism.

2 Isolation of infected individuals during the period of communicability

3. Immunization—Preventive vaccination by suspensions of mixtures of the *Micrococcus melitensis* and *Micrococcus paramelitensis* have given good results. This is advised for exposed susceptibles, especially those handling goats in areas where the disease is known to exist. Autogenous vaccines have been used with but little success in the treatment of the disease.

4 Quarantine—None

5. Concurrent disinfection of all discharges, especially the urine and of articles soiled with such discharges

6 Terminal disinfection—Cleaning.

(B) General measures—

1. Sterlization of goats' milk.

2. Protection of public water supplies

3 Supervision of human carriers and their exclusion from the handling of foods.

4 Destruction of infected animals

5. Search for infection among goats by the serum and the lacto reaction (Zammit).

6. Immunization of goats by vaccines in areas where the disease is prevalent.

7. Exclusion of goats from areas of infection.

8. Sanitary supervision of goat shelters.

Measles

1. *Infectious agent*.—Unknown.
2. *Source of infection*.—Buccal and nasal secretions of an infected individual.
3. *Mode of transmission*.—Directly from person to person, indirectly through articles freshly soiled with the buccal and nasal discharges of an infected individual. The most easily transmitted of all communicable diseases.
4. *Incubation period*.—About 10 days.
5. *Period of communicability*.—During the period of catarrhal symptoms and until the cessation of abnormal mucous membrane secretions—minimum period of nine days; from four days before to five days after the appearance of the rash.
6. *Methods of control*.

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms. Special attention to rise of temperature, Koplik spots and catarrhal symptoms in exposed individuals.
2. Isolation—During period of communicability.
3. Immunization—By the use of the serum or whole blood of convalescent measles patients, or of any healthy adults who have had measles, given within five days after exposure to a known case of measles, the attack in the exposed person may be averted in a high percentage of instances; if not averted, the disease is modified. Given later, but at a time prior to the clinical onset of the disease, convalescent serum usually modifies the severity of the attack and the patient acquires the usual lasting immunity to the disease.
4. Quarantine—Exclusion of exposed susceptible school children and teachers from school until 14 days from last exposure. This applies to exposure in the household. Exclusion of exposed susceptible children from all public gatherings for the same period.
5. Concurrent disinfection—All articles soiled with the secretions of the nose and throat.
6. Terminal disinfection—Thorough cleaning.

(B) General measures—

1. Daily examination of exposed children and of other possibly exposed persons. This examination should include record of the body temperature. A nonimmune exposed individual exhibiting a rise of temperature of 0.5° C. or more should be promptly isolated pending diagnosis.
2. Schools should not be closed or classes discontinued where daily observation of the children by a physician or nurse is provided for.
3. Education as to special danger of exposing young children to those exhibiting acute catarrhal symptoms of any kind.
4. In institutional outbreaks immunization with convalescent serum of all minor inmates who have not had measles is of value in checking the spread of infection and in reducing mortality.

Meningococcus Meningitis

1 *Infective agent*.—Meningococcus; *Neisseria intracellularis.*

2 *Source of infection*.—Discharges from the nose and mouth of infected persons. Clinically recovered cases and healthy persons who have never had the disease but have been in contact with cases of the disease or other carriers, act as carriers and are commonly found especially during epidemics. Such healthy carriers are not uncommonly found independent of epidemic prevalence of the disease.

3. *Mode of transmission*.—By direct contact with infected persons and carriers, and indirectly by contact with articles freshly soiled with the nasal and mouth discharges of such persons.

4 *Incubation period*.—Two to ten days commonly seven. Occasionally for longer periods when a person is a carrier for a time before developing the disease.

5 *Period of communicability*.—During the clinical course of the disease and until the specific organism is no longer present in the nasal and mouth discharges of the patient. The same applies to healthy carriers so far as affects persistence of infectious discharges.

6 *Methods of control*.

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms, confirmed by the microscopic and bacteriological examination of the spinal fluid, and by bacteriological examination of nasal and pharyngeal secretions.
2. Isolation of infected persons until 14 days after onset of the disease.
3. Immunization by the use of vaccines is still in the experimental stage.
4. Quarantine—None.
5. Concurrent disinfection of discharges from the nose and mouth and of articles soiled therewith.
6. Terminal disinfection—Cleaning.

(B) General measures—

1. Search for carriers among families and associates of recognized cases by bacteriological examination of posterior nares of all contacts.
2. Education as to personal cleanliness and necessity of avoiding contact and droplet infection.
3. Prevention of overcrowding such as is common in living quarters, transportation conveyances, working places, and places of public assembly in the civilian population, and in inadequately ventilated closed quarters in barracks, camps, and ships among military units.

(C) Epidemic measures—

1. **Increase the separation of individuals and the ventilation in living and sleeping quarters for such groups of people as are especially exposed to infection because of their occupation or some necessity of living conditions. Bodily fatigue and strain should be minimized for those especially exposed to infection.**
2. Carriers should be quarantined until the nasal and pharyngeal secretions are proved by bacteriological examination to be free from the infecting organism.

Mumps

1. *Infective organism.*—Unknown.
2. *Source of infection.*—Secretions of the mouth and possibly of the nose.
3. *Mode of transmission*—By direct contact with an infected person or with articles freshly soiled with the discharges from the nose or throat of such infected person.
4. *Incubation period.*—From 12 to 26 days. The most common period, 18 days, accepted as usual A period of 21 days is not uncommon
5. *Period of communicability*—Unknown, but assumed to persist until the parotid gland has returned to its normal size.
6. *Methods of control*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Inflammation of Stenson's duct may be of assistance in recognizing the early stage of the disease. The diagnosis is usually made on swelling of the parotid gland.
      2. Isolation—Separation of the patient from nonimmune children and exclusion of the patient from school and public places for the period of presumed infectivity (See 5)
      3. Immunization—None.
      4. Quarantine—None. Exposed susceptible persons should be regularly inspected for the onset, the presence of initial symptoms of the disease, such as fever, or swelling or pain of the parotid or adjacent lymph glands, for three weeks from the date of last exposure
      5. Concurrent disinfection—All articles soiled with the discharges from the nose and throat of the patient.
      6. Terminal disinfection—None.

   (B) General measures—
      None.

Paratyphoid Fever

1. *Infectious agent.*—Paratyphoid bacillus A or B. *Salmonella paratyphi; Salmonella schottmulleri*
2. *Source of infection*—Bowel discharges and urine of infected persons, and foods contaminated with such discharges of infected persons or of healthy carriers. Healthy carriers may be numerous in an outbreak.
3. *Mode of transmission*—Directly by personal contact; indirectly by contact with articles freshly soiled with the discharges of infected persons or through milk, water, or food contaminated by such discharges.
4. *Incubation period.*—Four to ten days; average, seven days.
5. *Period of communicability*—From the appearance of prodromal symptoms, throughout the illness and relapses, during convalescence, and until repeated bacteriological examination of discharges show absence of the infecting organism.
6. *Methods of control:*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, confirmed by specific agglutination test, and by bacteriological examination of blood, bowel discharges, or urine.
      2. Isolation—In fly-proof room, preferably under hospital conditions, of such cases as can not command adequate sanitary environment and nursing care in their homes.
      3. Immunization of exposed susceptibles.

6 *Methods of control*—Continued

(A) The infected individual and his environment—Continued.

4 Quarantine—None

5 Concurrent disinfection—Disinfection of all bowel and urinary discharges and articles soiled with them

6 Terminal disinfection—Cleaning.

(B) General measures—

1. Protection and purification of public water supplies.
2. Pasteurization of public milk supplies
3. Supervision of other food supplies and of food handlers [2]
4. Prevention of fly breeding.
5. Sanitary disposal of human excreta
6. Extension of immunization by vaccination as far as practicable.
7. Supervision of paratyphoid carriers and their exclusion from the handling of foods.
8. Systematic examination of fecal specimens, from those who have been in contact with recognized cases, to detect carriers.
9. Exclusion of suspected milk supplies pending discovery of the personal or other cause of contamination of the milk
10. Exclusion of water supply, if contaminated, until adequately treated with hypochlorite or other efficient disinfectant, or unless all water used for toilet, cooking, and drinking purposes is boiled before use

Plague

(Bubonic, Septicemic, Pneumonic)

1. *Infectious agent.*—Plague bacillus; *Pasteurella pestis.*
2. *Source of infection* —Blood of infected persons and animals, and sputum of human cases of plague pneumonia.
3. *Mode of transmission.*—Direct, in the pneumonic form. In other forms the disease is generally transmitted by the bites of fleas (*Xenopsylla cheopis* and *Ceratophyllus fasciatus*), by which the disease is carried from rats to man, also by fleas from other rodents. Accidental, by inoculation, or by the bites of infected animals. Bedbugs may transmit the infection; flies may possibly convey the infection
4. *Incubation period* —Commonly from 3 to 7 days, although occasionally prolonged to 8 or even 14 days.
5. *Period of communicability.*—Until convalescence is well established, period undetermined.
6. *Methods of control:*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms, confirmed by bacteriological examination of blood, pus from glandular lesions, or sputum. Animal inoculation of material from suspected cases.
2. Isolation—Patient in hospital if practicable; if not, in a screened room which is free from vermin [3]

---

[2] The human disease paratyphoid fever should not be confused with cases of food poisoning or infection due to enteritidis bacilli of animal origin

[3] In plague pneumonia, personal prophylaxis, to avoid droplet infection must be carried out by persons who come in contact with the sick Masks of closely woven cloth with mica windows should be worn over the head and to the shoulders. A long gown and rubber gloves drawn over the sleeves of the gown should be provided These articles should not be removed from the sick room until disinfected

6. *Methods of control*—Continued.

(A) The infected individual and his environment—Continued.

3. Immunization—Active immunization of those who may be exposed
4. Quarantine—Contacts for seven days
5. Concurrent disinfection—All discharges and articles freshly soiled therewith
6. Terminal disinfection—Thorough cleaning followed by thorough disinfection

(B) General measures—

1. Extermination of rats and vermin by use of known methods for their destruction, destruction of rats on ships arriving from infected ports; examination of rats, ground squirrels etc., in areas where the infection persists, for evidence of endemic or epidemic prevalence of the disease among them.
2. Supervision of autopsies of all deaths during epidemics
3. Supervision of the disposal of the dead during epidemics, whether by burial, transfer, or holding in vault, whatever the cause of death.
4. Cremation, or burial in quicklime, of those dying of this disease

Pneumonia

Acute Lobar

1. *Infectious agent.*—Various pathogenic bacteria commonly found in the nose, throat, and mouth, such as the pneumococcus, the bacillus of Friedlander, the influenza bacillus, etc.
2. *Source of infection.*—Discharges from the mouth and nose of apparently healthy carriers, as well as of recognized infected individuals, and articles freshly soiled with such discharges.
3. *Mode of transmission.*—By direct contact with an infected person, or with articles freshly soiled with the discharges from the nose or throat of, and possibly from infected dust of rooms occupied by, infected persons
4. *Incubation period.*—Short, usually two to three days.
5. *Period of communicability.*—Unknown; presumably until the mouth and nasal discharges no longer carry the infectious agent in an abundant amount or in a virulent form
6. *Methods of control*·

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms. Specific infecting organisms may be determined by serological and bacteriological tests early in the course of the disease
2. Isolation—Patient during clinical course of the disease.
3. Immunization—None; vaccines are worthy of further careful trial.
4. Quarantine—None.
5. Concurrent disinfection—Discharges from the nose and throat of the patient.
6. Terminal disinfection—Thorough cleaning, airing, and sunning.

(B) General measures—

In institutions and camps, when practicable, people in large numbers should not be congregated closely within doors. The general resistance should be conserved by good feeding, fresh air, temperance in the use of alcoholic beverages, and other hygenic measures.

NOTE.—The early reporting of pneumonia is highly desirable in view of its communicability.

Poliomyelitis

1. *Infectious agent*.—A filterable virus of undetermined morphology.
2. *Source of infection*.—Nose, throat, and bowel discharges of infected persons or articles recently soiled therewith. Healthy carriers are supposed to be common.
3. *Mode of transmission*.—By direct contact with an infected person or with a carrier of the virus, or indirectly by contact with articles freshly soiled with the nose, throat, or bowel discharges of such persons, and probably by drinking milk contaminated by the nose, mouth and bowel discharges of persons in the active stage of the disease.
4. *Incubation period*.—Uncertain because of inexact information as to period of communicability and essentials for exposure, but believed to be from 3 to 10 days, commonly 6 days.
5. *Period of communicability*.—Unknown; apparently not more than 21 days from the onset of disease, but may precede onset of clinical symptoms by several days.
6. *Methods of control*.
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, assisted by chemical and microscopical examination of the spinal fluid.
      2. Isolation of all recognized cases for three weeks from febrile onset.
      3. Immunization—None.
      4. Quarantine of exposed children of the household and of adults of the household whose vocation brings them into contact with children, or who are food handlers, for 14 days from last exposure to a recognized case.
      5. Concurrent disinfection—Nose, throat, and bowel discharges and articles soiled therewith.
      6. Terminal disinfection—Cleaning.
   (B) General measures during epidemics—
      1. Search for and examination of all sick children should be made.
      2. All children with fever should be isolated pending diagnosis.
      3. Education in such technique of bedside nursing as will prevent the distribution of infectious discharges to others from cases isolated at home.

Rabies

1. *Infectious agent*.—Unknown.
2. *Source of infection*.—Saliva of infected animals, chiefly dogs.
3. *Mode of transmission*.—Inoculation with saliva of infected animals through abrasion of skin or mucous membrane, almost always by bites or scratches.
4. *Incubation period*.—Usually two to six weeks. May be prolonged to 6 months or even longer.
5. *Period of communicability*.—For 15 days in the dog (not known in man) before the onset of clinical symptoms and throughout the clinical course of the disease.
6. *Methods of control*.
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, confirmed by the presence of Negri bodies in the brain of an infected animal, or by animal inoculations with material from the brain of such infected animal.

6. *Methods of control*—Continued.

(A) The infected individual and his environment—Continued.

2. Isolation—None if patient is under adequate medical supervision, and the immediate attendants are warned of possibility of inoculation by human virus
3. Immunization—Preventive vaccination after exposure to infection by inoculation.
4. Quarantine—None.
5. Concurrent disinfection of saliva of patient and articles soiled therewith.
6. Terminal disinfection—Thorough cleaning.

(B) General measures—

1. Muzzling of dogs when on public streets, or in places to which the public has access.
2. Detention and examination of dogs suspected of having rabies.
3. Immediate antirabic treatment of people bitten by dogs or by other animals suspected or known to have rabies, unless the animal is proved not to be rabid by subsequent observation or by microscopic examination of the brain and cord.
4. Annual immunization of dogs where the disease is prevalent.

Rocky Mountain Spotted or Tick Fever

1. *Infectious agent*—Unknown.
2. *Source of infection.*—Blood of infected animals, and infected ticks (dermacentor species).
3. *Mode of transmission.*—By bites of infected ticks
4. *Incubation period*—Three to ten days, usually seven days.
5. *Period of communicability.*—Has not been definitely determined, probably during the febrile stage of the disease.
6. *Methods of control*·

(A) The infected individual and his environment—

1. Recognition of the disease—By clinical symptoms of the disease in areas where the disease is known to be endemic.
2. Isolation—None, other than care exercised to protect patients from tick bites when in endemic areas.
3. Immunization—The use of the Spencer-Parker vaccine in infected areas has given generally favorable results, but is still in the experimental stage
4. Quarantine—None.
5. Concurrent disinfection—None All ticks on the patient should be destroyed
6. Terminal disinfection—None.

(B) General measures—

1. Personal prophylaxis of persons entering the infected zones during the season of ticks, by wearing tick-proof clothing, and careful daily search of the body for ticks which may have attached themselves.
2. The destruction of ticks by clearing and burning vegetation on the land in infected zones.
3. The destruction of ticks on domestic animals by dipping, and the pasturing of sheep on tick-infested areas where the disease is prevalent, with the object of diminishing the number of ticks.
4. The destruction of small mammalian hosts, as ground squirrels, chipmunks, etc.

Scarlet Fever

1. *Infectious agent.*—*Streptococcus scarlatinæ*
2. *Source of infection.*—Discharges from the nose, throat, ears, abscesses or wound surfaces, and articles freshly soiled therewith. The nose and throat discharges of carriers may also spread the disease.
3. *Mode of transmission.*—Directly by personal contact with an infected person; indirectly by articles freshly soiled with discharges of an infected person, or through contaminated milk, or milk products.
4. *Incubation period.*—Two to seven days, usually three or four days.
5. *Period of communicability.*—Three weeks from the onset of the disease, without regard to the stage or extent of desquamation, and only after all abnormal discharges have ceased and all open sores or wounds have healed.
6. *Methods of control.*—
   (A) The infected individual and his environment—
      1. Recognition of the disease—By clinical symptoms.
      2. **Isolation—In home or hospital, maintained in each case until the end of the period of infectivity.** If medical inspection is not available, isolation for 28 days from onset.
      3. Immunization—Exposed susceptibles as determined by the Dick test may be actively immunized by scarlet fever toxin.
      4. Quarantine—Exclusion of exposed children and teachers from school, and food handlers from their work, until seven days have elapsed since last exposure to a recognized case.
      5. Concurrent disinfection—Of all articles which have been in contact with a patient and all articles soiled with discharges of the patient.
      6. Terminal disinfection—Thorough cleaning.

   (B) General measures—
      1. Daily examination of exposed children and of other possibly exposed persons for a week after last exposure.
      2. Schools should not be closed where daily observation of the children by a physician or nurse can be provided for.
      3. In school and institutional outbreaks immunization of all exposed children with scarlet fever toxin may be advisable.
      4. Education as to special danger of exposing young children to those exhibiting acute catarrhal symptoms of any kind.
      5. Pasteurization of milk supply.

Septic Sore Throat

1. *Infectious agent.*—Streptococcus (hemolytic type).
2. *Source of infection.*—The human naso-pharynx, usually the tonsils, any case of acute streptococcus inflammation of these structures being a potential source of infection, including the period of convalescence of such cases. The udder of a cow infected by the milker is a common source of infection. In such udders the physical signs of mastitis may be absent.[4]
3. *Mode of transmission.*—Direct or indirect human contact; consumption of raw milk contaminated by case or carrier or from an infected udder.
4. *Incubation period.*—One to three days.

---

[4] Mastitis in the cow, due to bovine streptococci, is not a cause of septic sore throat in humans unless a secondary infection of the udder by a human type of streptococcus takes place.

5. *Period of communicability*—In man, presumably during the continuance of clinical symptoms, in the cow, during the continuance of discharge of the streptococci in the milk, the condition in the udder tending to a spontaneous subsidence. The carrier stage may follow convalescence and persist for some time.
6. *Methods of control*·
   (A) The infected individual and his environment—
      1 Recognition of the disease—Clinical symptoms Bacteriological examination of the lesions or discharges from the tonsils and naso-pharynx may be useful
      2 Isolation—During the clinical course of the disease and convalescence, and particularly exclusion of the patient from participation in the production or handling of milk or milk products
      3 Immunization—None.
      4 Quarantine—None
      5. Concurrent disinfection—Articles soiled with discharges from the nose and throat of the patient
      6. Terminal disinfection—Cleaning
   (B) General measures—
      1. Exclusion of suspected milk supply from public sale or use, until Pasteurized. The exclusion of the milk of an infected cow or cows in small herds is possible when based on bacteriological examination of the milk of each cow, and preferably the milk from each quarter of the udder at frequent intervals Exclusion of human cases or carriers from handling milk or milk products.
      2. Pasteurization of all milk
      3. Education in the principles of personal hygiene and avoidance of the use of common towel, drinking and eating utensils.

Smallpox

1. *Infectious agent.*—Unknown.
2. *Source of infection*—Lesions of the mucous membranes and skin of infected persons
3. *Mode of transmission*—By direct personal contact; by articles soiled with discharges from lesions. The virus may be present in all body discharges, including feces and urine. It may be carried by flies.
4. *Incubation period.*—Eight to sixteen days. (Cases with incubation period of 21 days are reported.)
5. *Period of communicability*—From first symptoms to disappearance of all scabs and crusts.
6. *Methods of control:*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms. Tests for immunity may prove useful
      2. Isolation—Hospital isolation in screened wards, free from vermin, until the period of infectivity is over.
      3 Immunization—Vaccination.
      4. Quarantine—Isolation of all contacts until vaccinated with virus of full potency. Daily medical observation of all recently vaccinated contacts until height of reaction is passed, if vaccination was performed within 24 hours of first exposure, otherwise for 16 days from last exposure.

6. *Methods of control*—Continued
   (A) The infected individual and his environment—Continued
      5. **Concurrent disinfection of all discharges.** No article to leave the surroundings of the patient without boiling or equally effective disinfection.
      6. Terminal disinfection—Thorough cleaning and disinfection of premises.
   (B) General measures—
      General vaccination in infancy, revaccination of children on entering school, and of entire population when the disease appears in a severe form.

NOTE.—In order to avoid possible complications or secondary and subsequent infections at the site of vaccination, it is important that the vaccination insertion be as small as practicable, not over one-eighth inch in any direction, and that the site be kept dry and cool. The prick-pressure method is recommended by the United States Public Health Service, or the single scratch method is preferred. Primary vaccination between the ages of two and three months is particularly desirable. The time of vaccination should be adjusted to avoid skin lesions elsewhere on the body, in infants to avoid teething, and in older children to avoid the warmer months. Particular care should be used in primary vaccinations beyond the age of infancy.

Syphilis

1. *Infectious agent.—Treponema pallidum.*
2. *Source of infection.*—Discharges from the lesions of the skin and mucous membranes, and the blood of infected persons, and articles freshly soiled with such discharges or blood in which the *Treponema pallidum* is present.
3. *Mode of transmission.*—By direct personal contact with infected persons, and indirectly by contact with discharges from lesions or with the blood of such persons.
4. *Incubation period.*—About three weeks. (In rare instances reported to have been as long as 70 days.)
5. *Period of communicability.*—As long as the lesions are open upon the skin, or mucous membranes at any stage of the disease.
6. *Methods of control.*
   (A) The infected individual and his environment—
      1. Recognition of the disease—Clinical symptoms, confirmed by microscopical examination of discharges and by serum reactions.
      2. Isolation—Exclusion from sexual contact and from preparation or serving of food during the early and active period of the disease; otherwise none, unless the patient is unwilling to heed, or is incapable of observing, the precautions required by the medical advisor.
      3. Immunization—None.
      4. Quarantine—None.
      5. Concurrent disinfection of discharges and of articles soiled therewith.
      6. Terminal disinfection—None.
   (B) General measures—
      1. Education in matters of sexual hygiene, particularly as to the fact that continence in both sexes and at all ages is compatible with health and normal development.
      2. Provision for accurate and early diagnosis and treatment, in hospitals and dispensaries, of infected persons, with consideration for privacy of record, and provision for following cases until cured.

Methods of control—Continued.

(B) General measures—Continued.

3. Repression of prostitution by use of the police power and control of use of living premises
4. Restriction of sale of alcoholic beverages
5. Restriction of advertising of services or medicines for treatment of sex diseases, etc.
6. Abandonment of the use of common towels, cups, and toilet articles and eating utensils
7. Exclusion of persons in the communicable stage of the disease from participation in the preparing and serving of food.
8. Personal prophylaxis should be advised to those who expose themselves to opportunity to infection.

Tetanus

1. *Infectious agent*—Tetanus bacillus, *Clostridium tetani*.
2. *Source of infection.*—Animal manure, soil, and street dust.
3. *Mode of transmission*—Inoculation, or wound infection
4. *Incubation period.*—Four days to three weeks, or longer if latent bacilli deposited in the tissues are stirred to activity by subsequent chemical or mechanical irritation Commonly 8 to 10 days.
5. *Period of communicability.*—Patient not infectious except in rare instances where wound discharges are infectious.
6. *Methods of control:*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms; may be confirmed bacteriologically.
2. Isolation—None
3. Immunization—By at least one, and preferably two, injections of antitoxin.
4. Quarantine—None.
5. Concurrent disinfection—None.
6. Terminal disinfection—None.

(B) General measures—

1. Supervision of the practice of obstetrics.
2. Educational propaganda such as "safety-first" campaign, and "safe and sane Fourth of July" campaign.
3. Prophylactic use of tetanus antitoxin where wounds have been acquired in regions where the soil is known to be heavily contaminated, and in all cases where wounds are ragged or penetrating.
4. Removal of all foreign matter as early as possible from all wounds.
5. Supervision of biological products, especially vaccines and sera.

Trachoma

1. *Infectious agent.*[1]—The chief, although not yet known to be the only, infectious agents are the hemoglobinophilic bacilli including the so-called Koch-Weeks bacillus.
2. *Source of infection.*—Secretions and purulent discharges from the conjunctivae and adnexed mucous membranes of the infected persons.

---

[1] It has not yet been proven that trachoma is due to one specific organism.

3. *Mode of transmission*.—By direct contact with infected persons and indirectly by contact with articles freshly soiled with the infective discharges of such persons.
4. *Incubation period*.—Undetermined.
5. *Period of communicability*.—During the persistence of lesions of the conjunctivæ and of the adnexed mucous membranes or of discharges from such lesions.
6. *Methods of control*.

   (A) The infected individual and his environment—
   1. Recognition of the disease.—Clinical symptoms. Bacteriological examination of the conjunctival secretions and lesions may be useful.
   2. Isolation—Exclusion of the patient from general school classes.
   3. Immunization—None.
   4. Quarantine—None.
   5. Concurrent disinfection of discharges and articles soiled therewith.
   6. Terminal disinfection—None.

   (B) General measures—
   1. Search for cases by examination of school children, of immigrants, and among the families and associates of recognized cases; in addition, search for acute secreting disease of conjunctivae and adnexed mucous membranes, both among school children and in their families, and treatment of such cases until cured.
   2. Elimination of common towels and toilet articles from public places.
   3. Education in the principles of personal cleanliness and the necessity of avoiding direct or indirect transference of body discharges.
   4. Control of public dispensaries where communicable eye diseases are treated.

Trichinosis

1. *Infectious agent*.—*Trichinella spiralis*.
2. *Source of infection*.—Uncooked or insufficiently cooked meat of infected hogs.
3. *Mode of transmission*.—Consumption of undercooked infected pork products.
4. *Incubation period*.—Variable; usually about one week.
5. *Period of communicability*.—Disease is not transmitted by human host.
6. *Methods of control*.

   (A) The infected individual and his environment—
   1. Recognition of the disease—Clinical symptoms, confirmed by microscopical examination of muscle tissue containing trichinæ.
   2. Isolation—None.
   3. Immunization—None.
   4. Quarantine—None.
   5. Concurrent disinfection—Sanitary disposal of the feces of the patient.
   6. Terminal disinfection—None.

   (B) General measures—
   1. Inspection of pork products for the detection of trichinosis.
   2. Thorough cooking of all pork products at a temperature of 160° F. or over.

Tuberculosis (Pulmonary)

1. *Infectious agent*—Tubercle bacillus (human), *Mycobacterium tuberculosis* (*hominis*)
2. *Source of infection*—The specific organism present in the discharges, or articles freshly soiled with the discharges from any open tuberculous lesions, the most important discharge being sputum. Of less importance are discharges from the intestinal and genito-urinary tracts, or from lesions of the lymphatic glands, bone, and skin
3. *Mode of transmission*—Direct or indirect contact with an infected person by coughing, sneezing, or other droplet infection, kissing, common use of unsterilized food utensils, pipes, toys, drinking cups, etc, and possibly by contaminated flies and dust.
4. *Incubation period*—Variable and dependent upon the type of the disease
5. *Period of communicability*—Exists as long as the specific organism is eliminated by the host Commences when a lesion becomes an open one—i e, discharging tubercle bacilli, and continues until it heals or death occurs.
6. *Methods of control*
   (A) The infected individual and his environment—
   1. Recognition of the disease—By thorough physical examination supplemented by use of the X ray and specific skin reactions when necessary and confirmed by bacteriological examinations of sputum or other materials.
   2. Isolation of such "open" cases as do not observe the precautions necessary to prevent the spread of the disease
   3. Immunization—None.
   4. Quarantine—None
   5. Concurrent disinfection of sputum and articles soiled with it. Particular attention should be paid to prompt disposal or disinfection of sputum itself, of handkerchiefs, cloths, or paper soiled therewith, and of eating utensils used by the patient.
   6. Terminal disinfection—Cleaning and renovation

   (B) General measures—
   1. Education of the public in regard to the dangers of tuberculosis and the methods of control, with especial stress upon the danger of exposure and infection in early childhood.
   2. Provision of dispensaries and visiting-nurse service for discovery of early cases and supervision of home cases
   3. Provision of hospitals for isolation of advanced cases, and sanatoria for the treatment of early cases
   4. Provision of open-air schools and preventoria for pretuberculous children.
   5. Improvement of housing conditions and the nutrition of the poor.
   6. Ventilation and elimination of dust in industrial establishments and places of public assembly.
   7. Improvement of habits of personal hygiene and betterment of general living conditions.
   8. Separation of babies from tuberculous mothers at birth.

Tuberculosis (other than Pulmonary)

1 *Infectious agent*.—Tubercle bacillus (human and bovine), *Mycobacterium tuberculosis* (*hominis et bovis*).

2 *Source of infection*.—Discharges from mouth, nose, bowels, and genito-urinary tract of infected humans, articles freshly soiled with such discharges, milk from tuberculous cattle, rarely the discharging lesion of bones, joints, and lymph nodes

3. *Mode of transmission*.—By direct contact with infected persons, by contaminated food, and possibly by contact with articles freshly soiled with the discharges of infected persons

4 *Incubation period*.—Unknown.

5. *Period of communicability*.—Until lesions are healed.

6. *Methods of control*

(A) The infected individual and his environment—

1 Recognition of the disease—Clinical symptoms confirmed by bacteriological and serological examinations

2 Isolation—None

3. Immunization—None.

4. Quarantine—None

5 Concurrent disinfection—Discharges and articles freshly soiled with them.

6 Terminal disinfection—Cleaning

(B) General measures—

1. Pasteurization of milk and inspection of meats

2 Eradication of tuberculous cows from milch herds used in supplying raw milk.

3 Patients with open lesions should be prohibited from handling foods which are consumed raw

Tularæmia

1. *Infectious agent*.—*Bacterium tularense; Pasteurella tularensis.*

2. *Source of infection*.—Wild rabbits and ground squirrels; also infected laboratory animals—infected flies (*Chrysops discalis*) and ticks (*Dermacentor andersoni*).

3 *Mode of transmission*.—By bites of infected flies and ticks and by inoculation through handling infected animals, as in dressing rabbits for market and cooking, or in performing necropsies on infected laboratory animals. Eye infections have been caused by contamination of the conjunctival sac with portions of the internal organs or with the body fluids of infected flies, ticks, and wild rabbits.

4. *Incubation period*.—From 24 hours to 9 days; average slightly more than 3 days.

5. *Period of communicability*.—There is no authentic record of transfer of the disease from man to man The infection has been found in the blood during the first two weeks; in conjunctival scrapings and in lymph glands up to 17 days; in the spleen taken at autopsy up to 26 days. Flies are infective for 14 days, ticks throughout their lifetime. Refrigerated wild rabbits are infective for three weeks.

6. *Methods of control:*

(A) The infected individual and his environment—

1. Recognition of the disease By clinical symptoms of the disease, by animal inoculation of infected material, and by agglutination reactions
2. Isolation—None.
3. Immunization—None
4. Quarantine—None
5. Concurrent disinfection Disinfection of discharges from the ulcer, lymph glands, or conjunctival sac
6. Terminal disinfection—None

(B) General measures—

1. Avoidance of the bites of, or handling of, flies and ticks when working in the infected zones during the seasonal incidence of the deer fly and tick.
2. The use of rubber gloves by persons engaged in dressing wild rabbits wherever taken, or when performing necropsies on infected laboratory animals. Employment of immune persons for dressing wild rabbits or conducting laboratory experiments Thorough cooking of meat of wild rabbits.

Typhoid Fever

1 *Infectious agent.*—Typhoid bacillus, *Eberthelda typhi.*

2. *Source of infection.*—Bowel discharges and urine of infected individuals. Healthy carriers are common.

3. *Mode of transmission.*—Conveyance of the specific organism by direct or indirect contact with a source of infection. Among indirect means of transmission are contaminated water, milk, and shellfish. Contaminated flies have been common means of transmission in epidemics.

4. *Incubation period.*—From 7 to 23 days, averaging 10 to 14 days.

5. *Period of communicability.*—From the appearance of prodromal symptoms, throughout the illness and relapses during convalescence, and until repeated bacteriological examinations of the discharges show persistent absence of the infecting organism.

6. *Methods of control.*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms, confirmed by specific agglutination test and bacteriological examination of blood, bowel discharges, or urine.
2. Isolation—In fly-proof room, preferably under hospital conditions, of such cases as can not command adequate sanitary environment and nursing care in their homes Release from isolation should be determined by two successive negative cultures of stool and urine specimens collected not less than twenty-four hours apart.
3. Immunization—Of susceptibles in the family or household of the patient who have been exposed, or may be exposed during the course of the disease.
4. Quarantine—None
5. Concurrent disinfection—Disinfection of all bowel and urinary discharges and articles soiled with them.
6. Terminal disinfection—Cleaning.

6 *Methods of control*—Continued.

(B) General measures—

1 **Protection and purification of public water supplies.**
2 **Pasteurization of public milk supplies.**
3 Supervision of other food supplies, and of food handlers
4 Prevention of fly breeding
5 Sanitary disposal of human excreta.
6 Extension of immunization by vaccination as far as practicable in communities where the disease is prevalent
7 Supervision of typhoid carriers and their exclusion from the handling of foods.
8 Systematic examination of fecal specimens from those who have been in contact with recognized cases, to detect carriers
9 Persons who fail to show a strongly positive Widal reaction and contemplate traveling, should protect themselves by vaccination
10 Exclusion of suspected milk supplies pending discovery of the person or other cause of contamination of the milk
11. Exclusion of water supply, if contaminated, until adequately treated with hypochlorite or other efficient disinfectant, or unless all water used for toilet, cooking, and drinking purposes is boiled before use

Typhus Fever

1. *Infectious agent.*—*Rickettsia prowazeki* is believed to be the causative agent.
2. *Source of infection* —The blood of infected individuals
3. *Mode of transmission.*—Infectious agent transmitted by lice. (*Pediculus corporis, P capitis*)
4. *Incubation period.*—Five to 20 days, usually 12 days.
5. *Period of communicability* —Until 36 hours have elapsed after the temperature reaches normal.
6. *Methods of control.*

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms. Confirmation by agglutination tests ("Weil-Felix" reaction).
2. **Isolation—In a vermin-free room. All attendants should wear vermin-proof clothing.**
3. Immunization—Methods for immunization not generally accepted.
4. Quarantine—Exposed susceptibles for 14 days after last exposure.
5. Concurrent disinfection—None.
6 Terminal disinfection—Destroy all vermin and vermin eggs on body of patient, if not already accomplished Destroy all vermin and eggs on clothing. Rooms to be rendered free from vermin.

(B) General measures—

Delousing of persons, clothing, and premises during epidemics, or when they have come or have been brought into an uninfected place from an infected community.

Whooping Cough

1. *Infectious agent.*—Pertussis bacillus of Bordet and Gengou, *Hemophilus pertussis.*
2 *Source of infection* —Discharges from the laryngeal and bronchial mucous membranes of infected persons (rarely also of infected dogs and cats, which are known to be susceptible)
3. *Mode of transmission* —Contact with an infected person or animal or with articles freshly soiled with the discharges of such person or animal
4. *Incubation period.*—Commonly seven days, almost uniformly within 10 days.
5. *Period of communicability* —Particularly communicable in the early catarrhal stages before the characteristic whoop makes a clinical diagnosis possible The catarrhal stage occupies from 7 to 14 days. After the characteristic whoop has appeared the communicable period continues certainly for three weeks. Even if the spasmodic cough with whoop persists longer than this it is most unlikely that the infecting organism can be isolated from the discharges. The communicable stage must be considered to extend from seven days after exposure to an infected individual to three weeks after the development of the characteristic whoop.
6. *Methods of control.*
   (A) The infected individual and his environment—
      1 Recognition of the disease—Clinical symptoms, supported by a differential leucocyte count, and confirmed where possible by bacteriological examination of bronchial secretions. A positive diagnosis may be made by bacteriological examination of laryngeal discharges as early as one week before the development of the characteristic whoop.
      2. **Isolation—Separation of the patient from susceptible children, and exclusion of the patient from school and public places for the period of presumed infectivity.**
      3. Immunization—Use of prophylactic vaccination recommended by some observers. Not effective in all cases
      4. Quarantine—Limited to the exclusion of nonimmune children from school and public gatherings for 10 days after their last exposure to a recognized case.
      5. Concurrent disinfection—Discharges from the nose and throat of the patient and articles soiled with such discharges
      6. Terminal disinfection—Cleaning of the premises used by the patient.
   (B) General measures—
      Education in habits of personal cleanliness and in the dangers of association or contact with those showing catarrhal symptoms with cough.

Yellow Fever

1. *Infectious agent.*—Unknown.
2 *Source of infection.*—The blood of infected persons
3. *Mode of transmission.*—By the bite of infected *Aedes ægypti* mosquitoes.
4. *Incubation period.*—Three to five days, occasionally six days.
5. *Period of communicability.*—First three days of the fever.

6 *Methods of control*:

(A) The infected individual and his environment—

1. Recognition of the disease—Clinical symptoms
2. Isolation—Isolate from mosquitoes in a special hospital ward or thoroughly screened room. If necessary the room or ward should be freed from mosquitoes by fumigation. Isolation necessary only for the first three days of the fever.
3. Immunization—None
4. Quarantine—Contacts for six days.
5. Concurrent disinfection—None
6. Terminal disinfection—None Upon termination of case the premises should be rendered free from mosquitoes by fumigation

(B) General measures—

Eliminate mosquitoes by rendering breeding impossible.

(C) Epidemic measures—

1. Inspection service for the detection of those ill with the disease.
2. Fumigation of houses in which cases of disease have occurred and of all adjacent houses.
3. Destruction of Aedes ægypti mosquitoes by fumigation; use of larvicides; eradication of breeding places.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Water and Milk Borne Diseases. L. A. Suggs. (Proceedings of the Eighth Texas Water Works Short School, Texas Section, January 18–23, 1926, pp. 15–18. Abstract by L. A. Suggs.)

The water-borne diseases treated by the author in this article include typhoid fever, dysentery, cholera, and hookworm. Typhoid fever is a sanitary problem of the first magnitude. An outbreak of the disease is a reproach to the sanitation of any community. The germ enters the human body by the mouth and passes out by the bowels and urine. Its normal habitat is the alimentary canal of man and it soon dies in any other medium, with the exception of milk in which it grows well. If exposed for 20 minutes to a temperature of 60° C. the germ will be destroyed.

Sanitation has practically eliminated cholera. Hookworm is carried by water but 90 per cent of the infections enter the human body through the skin. All dysenteries are considered under one head. They are carried in the same way as typhoid.

The diseases most commonly conveyed by milk are tuberculosis (all types), typhoid fever, diphtheria, scarlet fever, septic sore throat, Malta fever, summer complaint of children, and diarrhea and dysentery of adults which are referable to milk. Tuberculosis is the most frequent and widespread of all the major infections. Milk is responsible for more sickness and deaths than any other food, possibly as much as all other foods combined. Science points the way out, if society will apply the knowledge. The reason bacteria grow most

luxuriantly in milk is because it is most difficult of all foods to deliver clean, is most readily decomposed, and is the only standard article of diet obtained from animal sources consumed in the raw state Scientific filtration of water and the proper and intelligent inspection of milk have materially reduced those diseases within the last few years.

Viability of Bacillus Typhosus in Oysters During Storage. Fred O Tonney, M D , and John L. White, M. D. Journal of the American Medical Association, vol. 84, May 9, 1925, pp. 1403–1406. (Abstract by R. E. Tarbett.)

This article covers studies made in the laboratories of the Chicago Department of Health to determine the survival of *B typhosus* in stored, shucked and shell oysters. Shell oysters were allowed to remain in 4 per cent sea salt water to which a 24-hour culture of *B. typhosus* had been added for a period of 48 hours; temperature of the water 60° to 70° F. The *B. typhosus* count on the sea salt water was 200,000,000 per cubic centimeter. The oysters were stored at 70° and 45° F. One gallon of shucked oysters was contaminated by adding a 24-hour culture of *B. typhosus* and allowed to stand 48 hours at 70° F. Each oyster, with 10 cubic centimeters of liquor, was then placed in a test tube. Three lots were stored at 98°, 70° and 45° F. The oyster juice subsequent to inoculation showed 74,000,000 *B. typhosus* per cubic centimeter

Endo's medium was used for making counts and colonies checked.

The results for shell oysters showed that at a storage temperature of 70° F. the organism could be found in fairly large numbers up to the eighth day, all oysters being dead by the seventh day, and at the storage temperature of 45° F. up to the sixtieth day, at which time all oysters were dead. *B. typhosus* were found on the shells after 23 days storage.

The results for the shucked oysters showed that at a storage temperature of 98° F. the organisms disappeared between the first and fourth day, the oysters going sour during the first day. At a storage temperature of 70° F. the organism was found in a fairly large number on the seventh day, the oysters souring on the first day. At a storage temperature of 45° F., the organism was found on the twenty-second day, the oysters souring on the fifth day.

The results showed that the longevity of *B typhosus* in the oyster juice of both shell and shucked oysters varied with temperature at which stored, being prolonged with the lower temperature, and that the microorganisms survive for a longer period than do the oysters.

Nonthermophilic, Spore-forming Bacteria Associated with Pasteurizing Equipment. A. H. Robertson, M. W. Yale and R. S. Breed (New York State Sta. Tech. Bul. 119 (1926), pp. 3–11, Pl. 1). From

Experiment Station Record, U S. Dept. of Agriculture, vol. 55, No 3, August, 1926, p 268.

"The discovery of large rod-shaped, spore-forming bacteria in samples of Pasteurized milk which did not appear on agar plates or in the raw milk led to an investigation of the organisms of this type. A total of 140 cultures of such organisms was finally isolated from freshly Pasteurized milk, or from material scraped from the Pasteurizing equipment. Of these cultures 48 were identified as *Bacillus subtilis*, 29 as *B. mesentericus*, 22 as *B vulgatus*, 21 as *B. circulans*, 10 as *B. albolacitis*, 2 as *B. laterosporus*, 1 as *B. panis*, 1 as *B cereus*, and 1 as *B. mycoides* Five cultures were not identified

"It is concluded from the study that the presence of such organisms indicates that the Pasteurizing equipment has not been properly cleaned These types do not appear on agar plates because the vegetative cells and a large majority of the spores have been killed by Pasteurization."

Report on an Investigation of the Pollution of Lake Michigan in the Vicinity of South Chicago and the Calumet and Indiana Harbors, 1924–1925. U. S. Public Health Service, 69 pages. (Abstract by Arthur P Miller)

In the summer of 1924, the trustees of the Sanitary District of Chicago, the commissioner of health of the city of Chicago, the director of health of the State of Illinois and the commissioner of health of the State of Indiana jointly requested the Surgeon General of the Public Health Service to cooperate with them in a study of the sewage pollution of Lake Michigan in the area adjacent to the so-called Calumet district, lying partly in Illinois and partly in Indiana. This request was granted and after certain preliminary surveys work was begun on September 18, 1924, under the immediate direction of Sanitary Engineer H R. Crohurst, continuing until October 31, 1925. The report of the investigation in mimeograph form has recently been released.

Referring to the report, the study was intended to comprise as follows: "(1) Sanitary survey of the drainage area of the Calumet Rivers, bringing together such data as were already available from various sources and supplementing these by additional field surveys as required; (2) the bacteriological study of the waters of Lake Michigan in this region and of the public water supplies taken from it; (3) the collection and analysis of available data relative to the influence of existing pollution of these water supplies upon the public health."

A general discussion of the investigation, together with a statement of previous sanitary investigations, is first offered Included in this first section there are also discussions of the influencing meteorological conditions, the lake elevation and currents and ice covering.

Important data concerning industrial wastes are given in the second section, which covers the survey of existing sources of pollution in the district under study.

The summary of the investigation of industrial plants states the following: "A total of 123 industrial plants were surveyed in the Calumet district. One hundred and nine of these discharge practically no offensive waste liquids, water being used only for condensing and cooling purposes in the power plants or for cooling in manufacturing processes, either in closed systems or in contact with products from which little offensive or taste-producing substances could be derived. The remaining 14 plants which discharge wastes of sanitary significance may be divided into two groups. One group includes plants discharging wastes containing appreciable amounts of organic material that might, under certain conditions, give rise to nuisances near the point of discharge The second group includes plants discharging wastes containing possible taste-producing substances which affect water supplies, especially where chlorine is used in the treatment process."

The survey of sanitary sewerage is summarized in a table which sets forth the approximate distribution of sewer population in the Calumet district.

Physical, chemical, and bacteriological examinations of the waters of Lake Michigan are covered in the third section of this report in considerable detail. Discussions of the methods used for collecting and examining samples, as well as the laboratory technique and method followed in computing plate counts and *B. coli* index, are given. Following this there are discussions of the results of the various examinations made, as well as the different factors having a bearing on conditions existing Several pages are devoted to findings as related to the bacteriological quality of municipal water supplies taken from the lake.

Conclusions drawn are short and concise and will, therefore, be taken directly from the report:

"The pollution of Lake Michigan by sanitary sewage and industrial wastes discharged from the Calumet district in Illinois and Indiana, especially from Indiana, is such as to render the sources of water supply now used by Hammond, Whiting, and East Chicago unfit for that purpose, even with elaborate and efficiently operated purification plants.

"The source of water supply of Gary, Ind., though lying outside of the zone of grossest pollution, is also seriously contaminated but not beyond the capacity of modern purification processes to safeguard it.

"The water supplies drawn by the city of Chicago from the Sixty-eighth Street and Dunne cribs are also affected and at times may be seriously endangered by sewage pollution from the Calumet district.

"The water supplies taken from the lake north of the Chicago River appear to be beyond the zone of pollution from the Calumet

district and are receiving water of such quality that it can be satisfactorily purified by artificial processes, excepting the supplies of Waukegan and Lake Forest Although the pollution of these latter supplies is in no way chargeable to the Calumet district, and its discussion is beyond the scope of this report, the existing pollution in this area of the lake, north of the Sanitary District of Chicago, obviously demands attention and abatement.

"If the use of the lake as a source of water supply for the urban population in the area south of the Chicago River is to be continued, as seems inevitable, it is necessary, in the interest of the public health, that the water supply intakes be protected To remove the intakes beyond the zone of at least occasional gross pollution would require their extension very far into the lake, to a distance which is probably not practicable Moreover, in the absence of remedial measures it is to be anticipated that the existing zone of pollution would be extended with the increase in the population and development of the adjacent land area. Therefore the obvious remedy for the present intolerable situation is abatement of the existing pollution of the lake. The choice of methods to achieve this end involves engineering and economic problems which it is not within the province of this report to discuss There is no question, however, that abatement of the existing pollution is possible notwithstanding the difficulties which it may present; and it is certain that the need is imperative."

The appendices of the report included 29 tables and 27 diagrams, the title of each of which is given in the index and is descriptive of the data contained in the table or shown in the diagram.

Air Conditioning and its Hospital Application. W. J. McConnell. *The Modern Hospital*, vol. 27, No. 2, August, 1926, p. 45. (Abstract by Leonard Greenburg.)

This paper presents a superficial survey of the problem of ventilation of the hospital. The author points out that "acceptable standards for hospital ventilation are lacking," but maintains that the need for mechanically purifying, heating, and otherwise conditioning the air of occupied places is now well recognized. For this reason the author urges that hospitals be equipped with systems for washing, humidifying, and heating the air which is to be supplied to the various rooms. In closing, he attempts to show that the cost of artificial ventilation is less than that of natural window ventilation when one takes into account the lesser bed space which may be obtained when natural ventilation is used.

It would be unfair to the reader of the engineering abstracts to pass over this paper without pointing out that Doctor McConnell cites no evidence for the harmfulness of ordinary city dust, and likewise cites no authority for the amount of dust or odors which may be removed by the ordinary spray washer. The evidence concerning the relation of humidity to disease is still open to further proof; the New York State Commission on Ventilation, for example,

failed to find any relation between respiratory disease and humidity. And, lastly, Doctor McConnell appears to be laboring under some misapprehension that it is necessary to provide a larger floor space per person with the window than with fan ventilation in hospitals.

DEATHS DURING WEEK ENDED DECEMBER 4, 1926

Summary of information received by telegraph from industrial insurance companies for week ended December 4, 1926, and corresponding week of 1925. (From the Weekly Health Index, December 8, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Dec 4, 1926	Corresponding week, 1925
Policies in force	66, 183, 596	62, 275, 841

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended November 27, 1926, 41 States reported 2,389 cases of diphtheria. For the week ended November 28, 1925, the same States reported 1,893 cases of this disease. Ninety-nine cities, situated in all parts of the country and having an aggregate population of more than 30,100,000, reported 1,236 cases of diphtheria for the week ended November 27, 1926. Last year for the corresponding week they reported 880 cases. The estimated expectancy for these cities was 1,391 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-nine States reported 4,348 cases of measles for the week ended November 27, 1926, and 3,215 cases of this disease for the week ended November 28, 1925. Ninety-nine cities reported 773 cases of measles for the week this year, and 1,165 cases last year.

Poliomyelitis.—The health officers of 42 States reported 33 cases

of poliomyelitis for the week ended November 27, 1926 The same States reported 40 cases for the week ended November 28, 1925

Scarlet fever—Scarlet fever was reported for the week as follows: Forty-one States—this year, 3,499 cases, last year, 3,167 cases; 99 cities—this year, 1,245 cases; last year, 1,125 cases; estimated expectancy, 975 cases.

Smallpox—For the week ended November 27, 1926, 40 States reported 413 cases of smallpox Last year for the corresponding week they reported 464 cases Ninety-nine cities reported smallpox for the week as follows 1926, 32 cases; 1925, 89 cases; estimated expectancy, 48 cases One death from smallpox was reported by these cities for the week this year—at Indianapolis, Ind.

Typhoid fever—Four hundred and seventy-seven cases of typhoid fever were reported for the week ended November 27, 1926, by 41 States. For the corresponding week of 1925 the same States reported 566 cases of this disease Ninety-nine cities reported 70 cases of typhoid fever for the week this year and 76 cases for the corresponding week last year. The estimated expectancy for these cities was 87 cases.

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 93 cities, with a population of about 29,500,000, as follows: 1926, 773 deaths, 1925, 744 deaths.

City reports for week ended November 27, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended November 27, 1926, compared with those for a like period ended November 28, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, October 24 to November 27, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia.—Aden, Jeddah, Kamaran, Perim

Iraq.—Basrah.

Persia.—Mohammerah, Bender-Abbas, Bushire

British India.—Karachi, Chittagong, Cochin, Vizagapatam, Tuticorin, Bombay, Madras.

Portuguese Indies.—Nova Goa

Federated Malay States.—Port Swettenham.

Straits Settlements.—Penang.

Dutch East Indies.—Samarang, Batavia, Surabaya, Sabang, Makassar, Banjermasin, Palembang, Pontianak, Belawan-Deli, Padang, Samarinda, Tarakan, Menado

French Indo-China.—Saigon and Cholon.

Sarawak.—Kuching.

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao

Portuguese Timor.—Dilly

China.—Amoy, Shanghai (International Settlement)

Hongkong.

Macao

Formosa.—Keelung.

Japan.—Yokohama, Osaka, Nagasaki, Niigata, Tsuruga, Hakodate, Shimonoseki, Moji

Korea.—Chemulpo, Fusan

Manchuria.—Mukden, Changchun, Harbin, Antung, Yingkow.

Kwantung.—Port Arthur, Dairen.

U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island

New Guinea.—Port Moresby

New Britain Mandated Territory.—Rabaul and Kokopo.

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.

New Caledonia.—Noumea.

Fiji.—Suva.

Hawaii.—Honolulu.

Society Islands.—Papeete.

AFRICA

Egypt.—Port Said, Suez, Alexandria.

Anglo-Egyptian Sudan.—Port Sudan, Suakin

Eritrea.—Massaua

French Somaliland.—Jibuti

British Somaliland.—Berbera.

Italian Somaliland.—Mogadiscio.

Kenya.—Mombasa

Zanzibar.—Zanzibar.

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria.

Madagascar.—Majunga, Tamatave.

Portuguese East Africa.—Mozambique, Beira, Lourenco, Marques

Union of South Africa.—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

Dutch East Indies—Balikpapan | *Philippine Islands*—Manila, Iloilo, Jolo, Cebu Zamboanga

ALGERIA

Plague—Oran—Sfax—November 10, 1926—Plague has been reported in Algeria as follows. At Oran, November 12, 1926, one fatal case; near Sfax, November 10, seven small foci.

BRAZIL

Smallpox—Rio de Janeiro—October 17–November 13, 1926—During the four weeks ended November 13, 1926, 279 cases of small-pox with 187 deaths were reported at Rio de Janeiro, Brazil Population, estimated, 1,587,535.

Summary—From January 1 to November 13, 1926, a total of 3,880 new cases of smallpox with 2,092 deaths was reported at Rio de Janeiro, Brazil.

CANADA

Communicable diseases—Week ended November 20, 1926—The Canadian Ministry of Health reports cases of certain communicable diseases in five Provinces of Canada for the week ended November 20, 1926, as follows:

Disease	Nova Scotia	Quebec	Ontario	Manitoba	Saskatchewan	Total
Influenza	33			1		34
Smallpox			34	8	15	57
Typhoid fever		6	9	2	3	20

Communicable diseases—Ontario Province—November, 1926—Comparative.—During the month of November, 1926, communicable diseases were reported in the Province of Ontario, Canada, as follows:

Disease	1926		1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis		2		1
Chancroid	1		1	
Chicken pox	1,527		859	
Diphtheria	393		279	19
German measles	15		4	
Gonorrhea	157		143	
Influenza		7		14
Lethargic encephalitis	2			4
Measles	736		530	
Mumps	47		306	
Pneumonia		127		177
Poliomyelitis	8	1	3	1
Scarlet fever	546		514	4
Smallpox	95	1	31	
Syphilis	99		105	
Tuberculosis	84	42	139	75
Typhoid fever	46	5	76	10
Whooping cough	312	2	130	3

Smallpox.—During the month of November, 1926, smallpox was reported in the Province of Ontario at 20 localities, the greatest number of cases being reported at Toronto, viz, 34; at Peterboro, 22 cases were reported.

COLOMBIA

Measures against rats.—Information received from the National Board of Hygiene shows that the campaign against rats is carried out in the Republic of Colombia at the Pacific ports which are in proximity to Guayaquil. The appropriation for the work is divided between the ports of Buenaventura and Tumaco. At Buenaventura a permanent service of rat catching is maintained, the methods employed being traps and premiums offered for dead rats. Measures against rats are carried out at the Atlantic ports, but on a smaller scale and only when deemed urgent by the sanitary officials.

CUBA

Malaria—Santiago de Cuba.—Under date of November 27, 1926, 193 cases of malaria were officially reported in the city of Santiago de Cuba. Unofficial reports place the number at about 5,000 cases present in the city and suburbs.

EGYPT

Plague—Tanta District—November 9, 1926.—A case of plague was reported November 9, 1926, in the district of Tanta.

Summary—January 1–November 4, 1926.—During the period from January 1 to November 4, 1926, 141 cases of plague were reported in Egypt, as compared with 135 cases during the corresponding period of the year 1925.

PARAGUAY

Mortality from tuberculosis—Asuncion—June 27–October 30, 1926.—During the period June 27 to October 30, 1926, 65 deaths from tuberculosis were reported at Asuncion, Paraguay. Population, 65,000.

Prevailing diseases.—During the same period, bronchitis, influenza, and pneumonia were stated to be the prevailing diseases at Asuncion.

TUNISIA

Plague—November, 1926.—Under date of November 27, 1926, six centers of plague were stated to exist in Tunisia, with a total of 57 isolated cases. No case of plague was reported in the city of Tunis or its suburbs. The epidemic was stated to be an epizootic affecting only the wild rats of the farming country of the interior and to have no relation with the Mediterranean ports. No new case of plague has been reported at Zarzia since October 31, 1926.

UNION OF SOUTH AFRICA

Plague—Cape Province—October 17–23, 1926—During the week ended October 23, 1926, 4 cases of plague with 3 deaths were reported in the Cape Province, Union of South Africa, occurring according to locality as follows: *Kimberley District*, on farm in vicinity of Modder River Station, 1 fatal case, European, making a total of 3 European cases and 1 native case, all fatal, occurring on the same farm, from October 10 to 23, 1926; *Williston District*—cases, 3, deaths, 2

Smallpox, Durban, Natal—During the week ended October 23, 1926, 6 additional cases of smallpox were reported in Durban, Natal, occurring in immediate contacts with the first cases, making a total of 16 cases reported since the beginning of the outbreak. The case previously reported at Inanda was stated to have been chicken pox.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen C C PIERCE, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 DECEMBER 24, 1926 NO. 52

AN EPIDEMIOLOGICAL STUDY OF ENDEMIC TYPHUS (BRILL'S DISEASE) IN THE SOUTHEASTERN UNITED STATES

WITH SPECIAL REFERENCE TO ITS MODE OF TRANSMISSION

By KENNETH F MAXCY, Passed Assistant Surgeon, United States Public Health Service

At the beginning of this century it was generally held that typhus fever had disappeared from the United States except for an occasional case imported from Europe or from Mexico.[1]

In 1910 Dr Nathan E Brill (1898, 1910, 1911), of New York, called attention to a typhuslike disease occurring endemically in that city He hesitated to identify it as typhus because of its generally milder course and its occurrence under circumstances different from those usually associated with that disease He accordingly believed that he was dealing with a new clinical entity, "an infectious disease of unknown etiology" Cases of this type have since been known in the United States as Brill's disease.

In 1912 Anderson and Goldberger, who had previously reported on the experimental transmission of Mexican typhus ("tabardillo") to monkeys, were similarly successful in the inoculation of a Rhesus monkey with blood from a case of Brill's disease in New York. They found that, as in "tabardillo," one infection rendered monkeys immune to subsequent inoculations of the same passage virus. Furthermore, monkeys previously infected with Mexican typhus were thereafter found immune to Brill's disease, and vice versa. From these observations they concluded that Brill's disease was, in fact, identical with typhus fever, and this conclusion seems to have been quite promptly and generally accepted.

---

[1] August Hirsch, in his "Geographical and Historical Pathology" (Pub by the New Sydenham Society, London, 1883), states that

The proper era of typhus for the United States and Canada begins with the period when immigration from Ireland had set in on a large scale We thus explain the fact that the ports on the east coast of North America have been the headquarters of the disease, and that the largest contingent of the sick has been supplied by the immigrants themselves, or their countrymen with whom they had come in contact On the other hand, it is a noteworthy fact that the most careful search among the plentiful epidemiologic records in the literature of the United States fails to discover a single statement as to the occurrence of typhus in the Mississippi Valley or in the Western States, so that the greater part of the continent appears to enjoy absolute immunity from the disease, and in no part of the whole territory do endemic centers of typhus appear to have formed, notwithstanding importations on a large scale

Besides the Irish, immigrants from other countries of Europe were from time to time responsible for small outbreaks in the cities of the eastern United States.

The endemic center of typhus (tabardillo) in Mexico has in like manner from time to time supplied the States of the southwest with infected immigrants, who have given rise to small outbreaks.

During the year or two following, stimulated by these publications, a considerable number of reports of the occurrence of cases similar to those described by Brill appeared in medical literature. In addition to these and since that time cases of clinical typhus have continued to be reported to the Surgeon General of the United States Public Health Service each year from various parts of the United States, but particularly from the Atlantic seaboard and the States near the Mexican border.

A certain portion of these have been imported, or traceable to infection recently imported from foreign sources. When this has been the case the epidemiological picture has been such as is usually associated with typhus as known in the Old World. For instance, in the fairly numerous instances when typhus has been introduced from Mexico in the last 10 years (Pierce, 1917, Boyd, 1917; Cumming and Senfter, 1917; Armstrong, 1922, Tappan, 1926) the disease has been virulent, the mortality high, and the cases have been in persons obviously lousy or those in contact with them.

On the other hand, there remain a large number of sporadic cases of mild typhus which could not be traced to recent importation and occurring under circumstances which strongly suggested local origin of the infection. In regard to this so-called endemic typhus, Brill originally noted that the epidemiology presented points of difference from that which is generally assigned to typhus. He pointed out that the cases occurred sporadically, without traceable connection with each other, that they seldom, if ever, gave rise to new cases among those in contact with the sick person, that no localized outbreaks occurred, and finally, that their seasonal distribution differed from that of typhus. Later, accepting the identity of the virus with typhus as indicated by the work of Anderson and Goldberger, Brill (1920) was led to raise the question whether some vector other than the louse might not be concerned in the transmission. The same question is raised by Allan (1923) as a result of his observations upon a series of cases occurring in Charlotte, N. C.

In 1922, while detailed as acting State epidemiologist to the State Board of Health of Alabama, the writer had occasion to observe with Havens (Maxcy and Havens, 1923) a number of cases which were identified clinically as the endemic form of typhus described by Brill and which gave a positive Weil-Felix reaction. As the same question with regard to the mode of transmission arose in these cases, an epidemiological study was undertaken under instructions from the Surgeon General in cooperation with local health authorities, and has been continued up to the present. The opportunity for study has been especially favorable, since this section of the United States is little subject to immigration either from Europe or from Mexico; and with cases occurring in the smaller cities and towns one

could exclude more surely the possibility of constant reintroduction of the virus from exotic sources and trace association between cases, if it existed.

EVIDENCE OF PREVALENCE IN SOUTHEASTERN UNITED STATES

Aside from the group of cases occurring in Alabama and in Savannah, Ga., which form the basis of this report, evidence has been collected of the existence of mild typhus in other cities and towns in North and South Carolina, Georgia, and Florida.

The first report from this section of the country was that by Paullin in 1913, in which he described the clinical course of six cases seen by him in Atlanta, Ga. In 1914 Newell and Allan reported 4 cases from Charlotte, N. C. In a later report Allan (1923) gave a detailed account of 24 cases which had occurred in that city, and no contact could be traced with recent arrivals, or, indeed, between any two cases.

In a personal communication (1925) Dr. William A. Smith, chairman of the City Board of Health and Welfare of Charleston, S. C., informed the author that cases of Brill's disease occurred in that city from time to time; that a considerable number, about 15 in all, had been reported within a short space of time two or three years previously. A rapid examination of the records of one of the city hospitals for 1923–1925 by the author revealed three typical clinical cases. Dr. H. Clay Foster (1925) submitted a typical clinical history of a case with a positive Weil-Felix reaction in a woman apparently infected in Beaufort, S. C. Dr. T. P. Waring (1925), of Savannah, made a similar clinical diagnosis on a little girl brought to him from Estill, S. C.

Since the report of Paullin (1913) cases have continued to occur in Atlanta, Ga. Thus there were reported to the city health department in 1920, 1 case; in 1922, 8 cases, and in 1923, 6 cases of typhus. Dr. T. F. Sellers informs me that in the State laboratory from August, 1923, up to November, 1925, 11 blood specimens from patients resident in Atlanta had been found positive by the Weil-Felix reaction. Sydenstricker (1926) has reported 6 cases which have come under his observation at the university hospital, Augusta, and Dr. E. B. Murphey, 1925 (personal communication), of that city is authority for the statement that from 1 to 5 cases have occurred in that city each year since the disease was first recognized in 1915, and that he can recall having seen similar cases as far back as 1906. Information was also obtained through the State department of health of cases of mild typhus occurring during 1924 and 1925 at Waynesboro, Millen, Lagrange, West Point, Gainesville, and Albany, Ga.

For some years an occasional case of typhus has been reported from Jacksonville, Fla.; thus in 1924, 3 cases, in 1925, 2 cases; in 1926 (up to December), 10 cases. The disease has also been reported in Tampa, Dunedin, Jensen, St. Petersburg, Callahan, and Lakeland, Fla.

DATA AVAILABLE FOR PRESENT STUDY

The cases which form the basis of this report are (1) those reported in the State of Alabama, 1922 to 1925, (2) those reported in the city of Savannah, Ga., 1923 to 1925.

A special effort was made by the author and associates in the Alabama State Board of Health to secure full information of the

occurrence of the disease in that State The matter was given some publicity through the medium of the full-time county health officers, having jurisdiction over 50 per cent of the population, through papers read before the State medical society and through the press It is thought, therefore, that so far as the disease was recognized, fairly complete information of its occurrence was obtained. This applies especially to the city of Montgomery, where, with the cooperation of the local physicians, the disease was intensively studied.

During the period of observation a total of 104 cases of clinical typhus were reported in Alabama, 62 of which were confirmed by the Weil-Felix reaction performed in the State laboratories Forty-four of these cases, 28 of which were confirmed by the Weil-Felix, were in Montgomery. An epidemiological case history was made out for each case Of the 44 Montgomery cases the author investigated personally 28; 7 were investigated by Dr C. H. Leach, acting State epidemiologist, and 2 by Dr. L. C Havens, director of the State laboratories. The history form of the remaining 7 was made out from information supplied by the attending physician. Of the 60 cases distributed in other cities and towns of the State only 7 were personally investigated by the author, 1 by Doctor Leach, and 1 by Doctor Havens, information for the remaining 51 being obtained from the local health officer or the physician in attendance.

In Savannah Brill's disease had first been brought to the attention of the medical profession by the report of a case before the local medical society in 1915 by Dr. Lawrence Lee. Beginning in 1923, an epidemiological study of the disease has been conducted by the author in collaboration with Dr. Victor C. Bassett, city health officer. The matter has been brought to the attention of the medical society, and cordial cooperation in the study given by the medical profession of the city.

Of the total of 93 cases reported, 32 have been confirmed by the Weil-Felix reaction. A history form has not been kept, as in the Alabama cases, but attempt has been made to secure certain items of information in each instance; viz, identification, including place of residence and place of business, occupation, recent travel, date of onset, clinical course, contact with preceding cases, secondary cases, presence of lice or other vermin. A majority of the cases have been seen personally by Doctor Bassett during the acute illness. When this was not done the information desired was obtained either by a personal visit to the patient himself after convalescence or from the physician in attendance, or a combination of these. The author has accompanied Doctor Bassett on many of these visits.

IDENTIFICATION AS TYPHUS

It has been tentatively accepted that the disease with which we are dealing in the southeastern United States is typhus, because of

(1) Its clinical identification with Brill's disease (Maxcy, 1926).

(2) The Weil-Felix reaction

(3) The work of Anderson and Goldberger (1912), identifying the virus of Brill's disease with that of Mexican "tabardillo"

(4) The successful transmission of the disease to Rhesus monkeys and to guinea pigs from cases in Savannah and Montgomery by the author, and the character of the reaction in these animals. (Unpublished report.) Further studies of the activity of this virus in experimental animals and its relation to the European virus are in progress.

However, granting that the identification of this disease with typhus may be questioned, it may at least be said that the cases here referred to form a clinical group as distinct and as homologous as measles, that they resemble typhus fever much more closely than they resemble any other recognized specific infection, and that as yet they have not been differentiated from that disease It is in this sense, then, that the designation "endemic typhus" is used in this paper.

EPIDEMIOLOGICAL CHARACTERISTICS

(*a*) *Distribution in Alabama.*—The distribution of the Alabama cases by cities and towns for each of the four years of observation is given in Table I. A majority of these cases occurred in the large cities, Birmingham, Mobile, and Montgomery, the remainder in the small towns. None have so far been reported from isolated country districts, although three of the cases from Covington County during the past year lived on farms.[2]

The disease appears to be largely if not entirely confined to the southern part of the State. The city of Birmingham has three times the population of Mobile and four times that of Montgomery, and yet it has reported only 7 cases as compared with 21 for Mobile and 44 for Montgomery. Inasmuch as the disease has been brought to the attention of the medical profession in Birmingham, and the reporting of communicable diseases is as good in this city as in the others, it is considered unlikely that the difference in incidence is attributable to undiscovered cases. Furthermore, diligent inquiry among physicians and health officers practicing in that part of the State which lies north of Birmingham has failed to reveal a single case during the four-year period.

[2] Dr. H. P. Rankin, county health officer, reports that during 1926 in Coffee County, adjoining Covington, there have been diagnosed 15 cases of Brill's disease These cases were widely distributed in the rural areas of the county and without traceable association.

TABLE I.—*Distribution of cases of endemic typhus in Alabama during four years of observation*

City or town	Population 1920	1922	1923	1924	1925	Total	Confirmed by Weil-Felix
Birmingham	178,806	1	3	2	1	7	4
Montgomery*	43,464	6	6	8	24	44	28
Mobile	60,777	2	------	2	17	21	12
Atmore	1,775	------	------	------	1	1	1
Brewton	2,682	------	------	1	------	1	1
Red Level	385	------	------	------	1	1	1
Andalusia	4,023	------	1	------	5	6	6
Opp	1,556	------	------	------	1	1	1
Troy	5,696	------	2	2	2	6	2
Sampson	1,646	------	1	1	2	4	2
Hartford	1,561	------	1	------	------	1	1
Dothan	10,034	------	------	------	6	6	1
Headland	1,252	2	------	------	2	4	1
Kinston	163	------	------	------	1	1	1
Total	--------	11	14	16	63	104	62

The intermittent occurrence of cases in the small towns is notable. For example, in Troy, Ala., a town of 5,696 population, case T2 became ill on November 18, 1923, case T3 on December 6, 1923, case T5 on March 25, and case T6 on March 26, 1924. No further cases occurred in this town so far as could be ascertained until November, 1925, a year and a half later, when a woman living next door to the house in which case T3 had resided came down with the disease In Sampson, population 1,646, there was a case in 1923; after a period of 14 months another case occurred. In Headland, population 1,252, there were 2 cases in 1922, and no more recognized or reported until 1925. The same characteristic is evident in the time distribution of the Montgomery cases, shown in Table II. A period of 3 to 6 months sometimes elapsed before a new case was reported.

From the information available, therefore, the disease is not uniformly distributed in Alabama. It occurs in certain cities and towns of the southern part of the State Its occurrence is scattered as regards place and time.

(*b*) *Age*—The series of cases is not sufficiently large to permit of a detailed analysis of the age distribution in comparison with that of Old World typhus. By reference to the ages of the Montgomery and Savannah cases, given in Tables III and IV, however, it will be seen that only 3 of 137 cases here recorded were in children under 10 years of age In the first 255 cases recorded by Brill his youngest case was 10 years of age, and there were relatively few under 20.

The mildness of typhus in children is a phenomenon well known to European observers. The consequently greater difficulty of clinical recognition may account for the low incidence recorded in this age group. It is also possible that differences in exposure may play a rôle.

(c) *Sex*—As indicated by Tables V and VI, *the incidence is almost twice as high in the male* as in the female in both the Montgomery and Savannah cases, taken as a whole Of the 24 cases reported by Allan (1923) in Charlotte, N. C, 19 were men. Of 50 cases selected for analysis by Brill (1910) 34 were males. The disproportionately high incidence of the endemic typhus of the United States among men may be due either to greater exposure to infection or to greater susceptibility.

(d) *Race*—In the eastern cities, Boston, New York, and Philadelphia, a large proportion of the cases of Brill's disease have been in persons born in Russia, and in southern Texas and California cases were chiefly among Mexicans, *but in the Southeastern States all the cases, with one or two possible exceptions, have occurred in native-born white Americans* The negro for some unknown reason is almost exempt For example, in Savannah, where negroes in 1920 constituted 47 per cent of the population, only 2 of the 93 cases recorded were in this race, in Alabama, where the population of the State is approximately one-third negro, only 2 of the 104 cases recorded were in negroes Allan remarked upon the absence of cases among this race in Charlotte, N. C

The question arises whether this apparent freedom of the colored race from the disease is a fact or whether it is simply due to lack of recognition and reporting of the disease in this race. The single case in a negro which I personally observed was typical in all respects, very severe, with a well-developed and plainly evident eruption as easily recognizable as in a white person. Practically all the physicians who recognized and reported cases among white people see in their routine practice a certain number of negroes. In Alabama a large proportion of the cases of continued fever, particularly where typhoid is suspected, are seen by the whole-time health officers. At Savannah, at Montgomery, and at Mobile a large number of the blood specimens which were submitted to the public health laboratories for the Widal test, as well as a considerable number of sera submitted for the Wassermann tests, were run against the Weil-Felix organism, with negative results so far as negroes are concerned, although by the same procedure a number of unrecognized cases among white persons were uncovered. With the available evidence, therefore, while the low incidence among the colored race may be in part accounted for by lack of recognition and reporting, this factor would seem not to account for all of the discrepancy. *The relative freedom of the negro from the disease is a fact which remains to be explained.*

(c) *Seasonal distribution.*—

TABLE II.—*Seasonal distribution of cases*

	Year	Jan	Feb	Mar.	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Total
Savannah, Ga	1923	-----	-----	-----	-----	-----	-----	7	8	6	11	5	1	38

		1	2	1	2	1	2	3	8	8	3	8	5	44
Other cities and towns in Alabama	1922	-----	-----	-----	-----	-----	-----	4	1	-----	-----	-----	-----	5
	1923	-----	1	-----	-----	-----	-----	-----	-----	2	1	2	2	8
	1924	-----	-----	2	-----	-----	1	-----	2	-----	1	1	1	8
	1925	2	-----	-----	-----	3	2	5	7	4	4	6	6	39
		2	1	2	-----	3	3	9	10	6	6	9	9	60
Grand total	-----	5	3	5	5	9	6	29	33	25	30	28	19	197

A tabulation of the cases reported by months (see Table II) shows that although the disease occurs in all months of the year, it reaches maximum incidence in the summer and fall. This characteristic has been constant through the four years of observation.

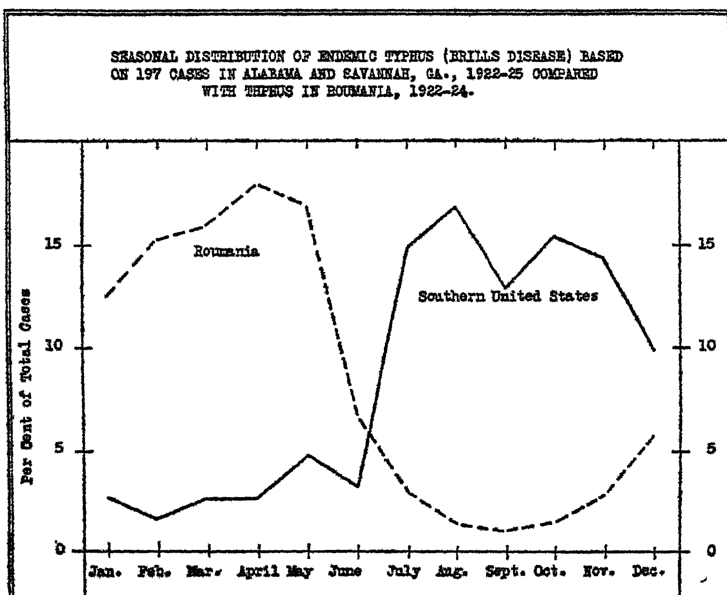

Fig. 1.

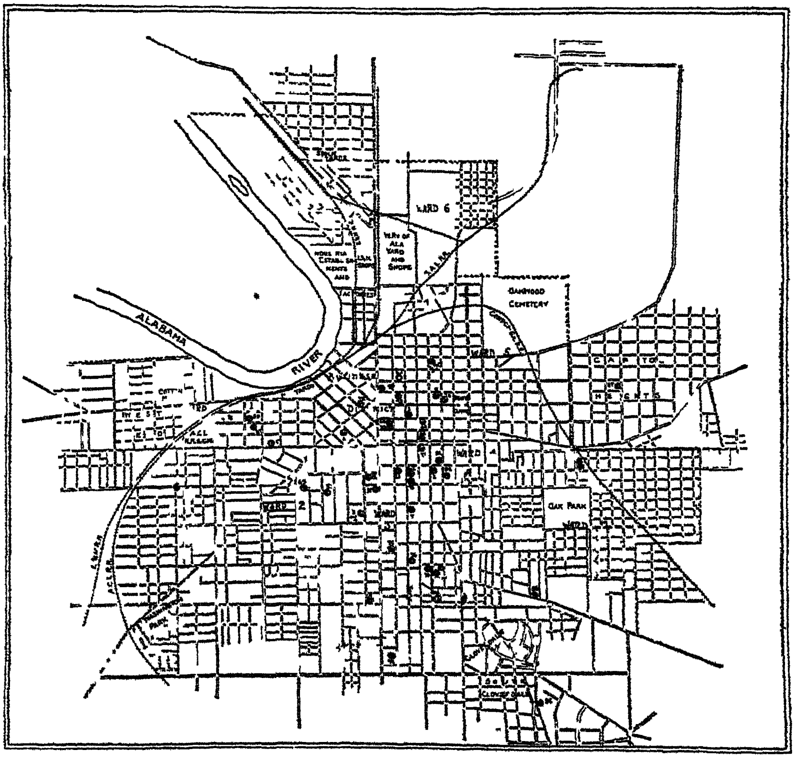
A similar seasonal distribution was found in New York City by Brill, who in his last report (1920), based upon an experience of 500 cases over a period of some twenty-odd years, stated that 70 per cent occurred from June to November.

The summer and fall maximum of the endemic typhus of the United States is in direct contrast with the high winter and spring incidence of typhus in the Old World. This is shown in the accompanying graph, in which the curve given by seasonal distribution of the 197 cases of endemic typhus which are analyzed in this report is compared with the curve for typhus in Rumania, 1922–1924 (League of Nations, 1925). The seasonal distribution of the disease in Russia, 1920–1924, and in Poland, 1922–1924, is similar to that of Rumania. Typhus is



MAP No 1.—Cases of mild typhus (Brill's disease) in Montgomery, Ala., 1922–1925, spotted according to residence

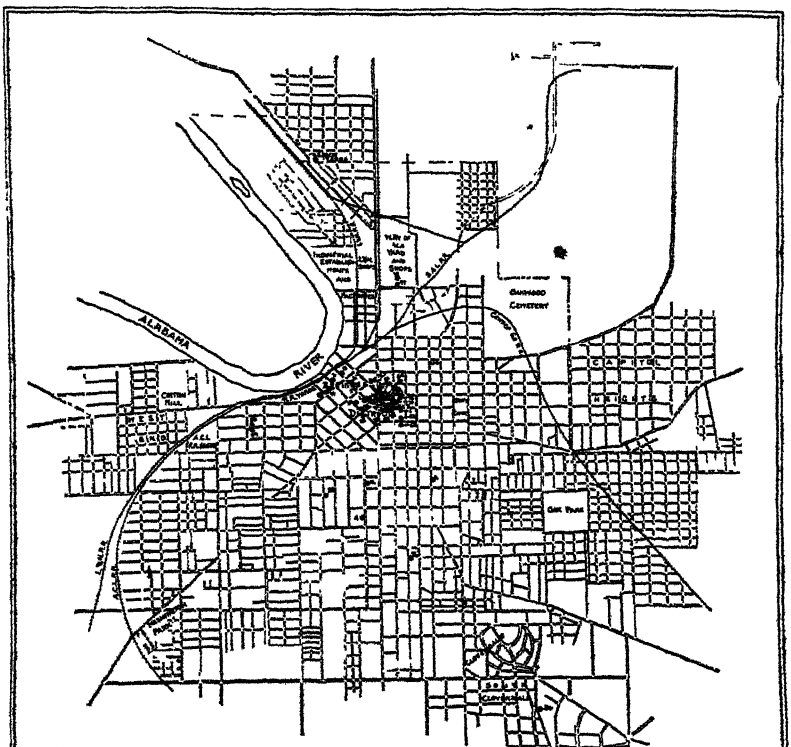
generally accepted to be a disease of the colder months; but the endemic disease of the United States is at a minimum during the colder months.

(*f*) *Location by residence.*—A study of the cases which occurred in Montgomery, located according to place of residence, as shown in map No. 1, suggests a tendency toward focalization in the central portion of the city in and near the business district. The question arises whether this apparent concentration is merely the result of a greater density of population in that part of the city. The 39 cases

living within the city limits were distributed among the seven city wards as follows:

Ward	Population, United States census 1920	Number of cases	Case rate per 1,000 population	Ward	Population, United States census 1920	Number of cases	Case rate per 1,000 population
1	5,636	4	0.71	5	5,044	4	0.74
2	9,405	4	.43	6	4,075	4	.98
3	4,147	8	1.98	7	8,122	5	.62
4	7,035	10	1.42				

This division of the city is peculiarly unfavorable for the purposes in mind, inasmuch as the wards are arranged radially in such manner that all except one (ward 7) include portions of the central part of



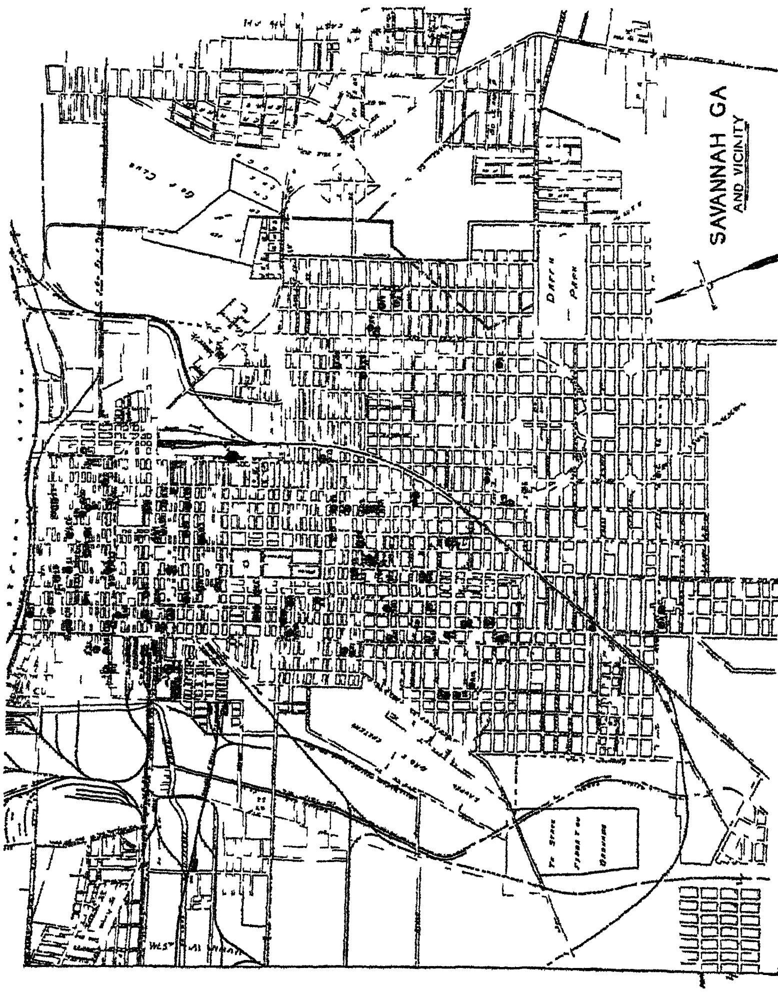
MAP NO 2.—Cases of mild typhus (Brill's disease) in Montgomery, Ala., 1922-1925, spotted according to place of employment, or if unemployed according to place of residence

the city. Even though this be true, the tabulation indicates a slight excess of cases in wards 3 and 4, which include a large portion of the older residential section bordering upon the business district.

In map No. 3 the Savannah cases have in like manner been shown according to their places of residence. The distribution appears to

be rather general, except perhaps for the newer residential portions and the outlying districts, where the incidence is apparently light. Population figures by wards for this city are not available in the United States census, and it is therefore not possible to compare rates for the different sections.

Summing up the data on location of cases by residence in both cities, one is impressed with the fact that the cases are scattered in

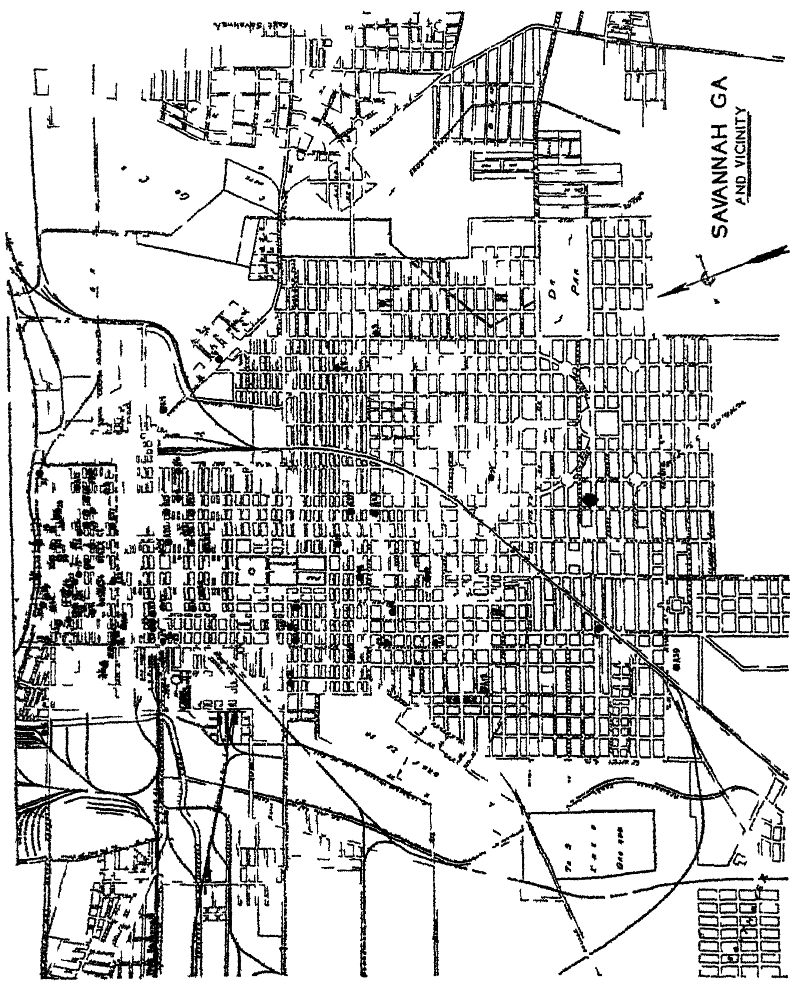


MAP No 3 —Cases of mild typhus (Brill's disease) in Savannah, Ga., 1923-1925, spotted according to residence

the sense that *there are no sharply localized neighborhood outbreaks.* However, there seems to be a tendency for the cases to occur more frequently in the older, more centrally located residential districts.

(*g*) *Location by place of business.*—Since an employed person is exposed to an even greater number of contacts at the place of business than in his home, the grouping of cases on this basis was also exam-

ined In map No 3 the Montgomery cases have been indicated according to place where employed, or if unemployed according to residence *This map suggests a focal center of the disease in the heart of the business district* A large proportion of the cases were employed (or lived, if unemployed) within four city squares of the corner of North Court and Monroe Streets This section of the



MAP NO 4 —Cases of mild typhus (Brill's disease) in Savannah, Ga, 1923 1925, spotted according to place of employment, or if not employed within the city limits according to residence

business district is largely made up of retail stores and markets, clothing stores, drug stores, grocery stores, butcher shops, fruit stands, seed and grain stores, etc

In map No. 4 the Savannah cases have been spotted in like manner according to place where employed, or if unemployed within the city, according to residence There is a similar grouping in the retail business section, but the disease is not so sharply focalized as in

Montgomery. Attention is called particularly to the point marked by a cross, the location of the food-marketing center of the city.

(*h*) *Occupation.*—The apparent focalization of the disease in the business district may be due to a concentration of employed persons in this area, or to a greater risk in certain occupations which are located in this part of the city. Evidence on this point has been obtained by an analysis of the cases according to the broad occupational groupings afforded by the United States census and presented in Tables V and VI.

In Montgomery 18 of the 29 cases in males (62 per cent) were engaged in "trade" (clerks, proprietors, managers, salesmen, dealers, etc), although only 23 per cent of the total number of occupied males over 10 years of age are so engaged. Only 1 case occurred among the 4,114 men employed in "manufacturing and mechanical industries"; 3 among the 2,608 men in "transportation." The 3 cases charged to "domestic and personal service" were employed in restaurants.

Similarly, in Savannah 23 of the 52 males (44 per cent) were in "trade," although only 17 per cent of the total number of occupied males are so engaged. The rates in "manufacturing and mechanical industries" and in "transportation" are comparatively low. In "agriculture, forestry, and animal husbandry" the cases consisted of 4 employed by dairies and 2 retired farmers; in "domestic and personal service" 4 employed in restaurants, 1 barber, and 1 hotel keeper.

Among employed females the distribution is much the same in both cities, though the groups are small. In both instances the highest incidence is found in "trade," the rate being approximately the same as for males in this group alone.

Using a different basis of classification, and the occupations as given in Tables III and IV, it is notable that in Montgomery 10 of the 32 employed persons (31 per cent) who had typhus were engaged in handling foods, groceries, meat, produce, feed, flour, or were employed in feed stores and restaurants. In Savannah 20 of 59 employed persons (34 per cent) having the disease were so engaged. The apparent excess of cases among food handlers is strikingly similar in the two cities, as are the rates for both males and females in "trade."

These analyses of the occupations of persons attacked by endemic typhus suggest very strongly that as compared with the rest of the population those engaged in "trade," and especially those employed in food depots, groceries, feed stores, and restaurants, are exposed to a distinctly increased risk of infection.

(*i*) *Social status.*—The occupational analysis also brings out the fact that the disease attacked, for the most part, persons earning a

reasonably good livelihood. There is a notable absence of cases among unskilled laborers and unemployed males

From personal observation of the cases and their surroundings the author and his collaborators are convinced that the disease did not select the poor and uncleanly It occurred among all classes The cases so far as they were discovered present a fair cross section of the social strata of the average American community This implies that a great majority of the cases were in persons cleanly in their homes and in their personal habits

There were no cases among the inmates of jails, prisons, or asylums There was no particular association of the disease with cheap boarding or rooming houses. The time-honored characteristics of Old World typhus were entirely lacking in this respect

(*j*) *Contact between cases* —One of the items of information on the case history form used in the Alabama series was, "History of Contact with Antecedent Case." In only one instance among the 44 cases in Montgomery was the patient or the physician in attendance or the investigator able to state that there was definite close association within three weeks prior to onset with a case of the same disease or a suspected case. The one exception was case No 4, who came down eight days after her husband

Of the 60 cases occurring in other parts of Alabama for whom a case history form was filed, in no instance was the patient or his physician aware of contact of the type described with a preceding case

The same statement holds true for the Savannah cases with the following exceptions:

Case 32 came down about seven days after his wife and two children had become ill with the same disease.

Case 27, onset July 5; case 35, onset July 27; and case 39, onset August 7, were employed in a large wholesale grocery store They were thus in casual contact at their place of business.

Case 28, onset June 25; case 32, onset July 9; and case 36 (fatal), onset August 12, worked on the same dairy farm and were in contact in their work. It will be noted that these cases occurred about the same time as those in the wholesale grocery store noted above. The dairy purchased feed from this store during the period involved, but personal contact of the men on the dairy farm with the men in the store could not be demonstrated. There were no known cases of typhus among the 100 or more patrons of the dairy.

It is thus seen that known contact with a preceding case is a very rare finding. It must be admitted, of course, that close contacts may have existed but were undiscovered, particularly in those cases in which dependence was placed entirely upon information supplied by the attending physician and his patient. On the other hand,

it seems quite unlikely that any considerable number of actually traceable contacts with sick persons or convalescents should have been overlooked

Moreover, there is evidence from another angle that the disease as observed in this study was not readily communicable from person to person. For each case that occurred there were a number of persons in intimate contact with the patient, including other members of the family, physicians, nurses, and visitors Notwithstanding the absence of prophylactic measures, infections among these known intimate contacts were rare

Among the 197 cases on which this report is based there were only two instances, noted above, in which more than one case occurred in a family in such sequence as to suggest the possibility that the earlier case might have infected the later one.

Eighteen of the 93 Savannah cases and 6 of the 44 Montgomery cases were hospitalized No effort was made to delouse the patient upon admission to the hospital; no precautions whatever were taken with regard to lice Not a single case has occurred among nurses attendants, physicians, or fellow patients. One physician had the disease in Montgomery, but he stated positively that he had not attended a case of known or suspected typhus for at least one month before the onset of his illness

Brill (1920) states that in over 500 cases of endemic typhus observed by him in New York City there have been only two instances in which more than one member of a family has been infected with the disease at the same time or nearly the same time Many of the New York cases have been hospitalized, from 15 to 30 being reported in that city each year since 1912, but no contact cases among patients, nurses, or doctors have been reported.

Allan (1923) was unable to trace any contact from case to case at Charlotte, N C In this connection mention should also be made of the numerous other cases reported in the literature and to the Surgeon General which have been sporadic and without secondary spread.

By way of contrast attention is called to Boyd's report (1917) of a small outbreak of Mexican typhus ("tabardillo") in Iowa. During 1915–1918 a considerable epidemic of "tabardillo" raged in Mexico, and as a consequence sporadic outbreaks were originated in American territory by imported laborers. A Mexican laborer was admitted to the Santa Fe Railroad hospital, Fort Madison, Iowa. It was later discovered that he had typhus, and lice were found upon his clothes. Following the diagnosis of his case, the physician who examined him on admission, the nurse who took charge of his clothing, two male nurses who attended him, and two other hospital patients came down with the disease within 30 days.

The lack of traceable relationship between cases and the extremely low secondary familial attack rate is a striking and constant characteristic of the endemic typhus of the United States.

Multiple cases on the same premises.—Although cases have so rarely been observed in the same family in such close sequence as to suggest communication of the disease during its acute febrile stage, several instances have been noted in which cases recurred on the same premises separated by intervals of six months or more

In Montgomery Mrs. R , living at ——— Columbus Street, had a typical attack of Brill's disease in December, 1922 Three years later, in September, 1925, while living at the same address, her husband had the disease.

In Savannah, at ——— Abercorn Street, there is an old frame building with a store on the first floor and a housekeeping flat on the second In August, 1923, a butcher who operated a meat market in the rear of the store had typhus Eighteen months later, in January, 1925, his father-in-law, who lived with him and also assisted him in the meat shop, had the disease In the flat above the store lived a family of nine persons; they had occupied these premises for eight years with the exception of six months in 1924. One of this family, Mrs. M., had the disease in August, 1925, seven months after the preceding case Although treated at home, there were no other cases in the family, nor was it possible to obtain a history of any previous cases in this family.[3]

Louse infestation—In view of the evidence that the disease is typhus, and that typhus, as known in the Old World, is transmitted from man to man by the louse, as careful inquiry as possible was made in each case to detect lice or any evidence suggesting prior infestation with them This inqury consisted in asking the physician in attendance and the patient, in all cases investigated, whether louse infestation had been noticed, or, indeed, whether the patient had noticed insect bites of any kind. In all cases investigated by the author in Alabama and in the few seen in Savannah search was made for nits or live insects on the hair of the head and body and on the bedclothes, and for scratch marks on the skin which might suggest infestation; at the same time other members of the family who were present were inspected and the environment was surveyed with the same purpose in view. Doctor Bassett has made the same search in all patients sick with this disease which he has seen in Savannah;

[3] In addition to these instances, two more have been noted in 1926. In the large wholesale grocery and feed store to which reference has been made under "Contact," in which three cases occurred during the summer of 1925, the manager became ill with the disease in August, 1926, no cases having occurred among other employees, so far as could be ascertained, in the meantime. A lunch room near by, in which case No. 1 (July, 1923) was employed, recently changed owners, and the new owner, case S48, came down with the disease in August, 1926. In the same neighborhood D K., a dealer in hides, furs, and chickens, was taken ill in June, 1926, followed by another worker in the same establishment six weeks later. There were no cases among the family contacts of either.

in addition, in some few instances, he has carefully searched the clothing worn by the patient prior to his illness. Every physician who has attended a case of Brill's disease which came to the author's attention has been questioned with regard to the presence of lice on his patient.

In Alabama such inquiry has been uniformly negative, except that in 1 out of 104 cases there was a history of a young girl living in the same house with the patient having had head lice three months previous to the onset

The inquiry in the 93 cases in Savannah was similarly negative with two exceptions: In case S12, 1923, proprietor of a cheap clothing store, a Jew, the attending physician made a positive statement that he had seen lice on the person and bed of the patient, in case S15, a negro, clinically positive for typhus, a health department inspector who had been sent to clean up the premises of the patient after his removal to the hospital stated that he had seen vermin on the bedclothes In neither instance were there secondary cases in the household or among the known contacts of the patient.

While this evidence does not in any single case exclude the possibility that the patient may have been bitten by one or more lice prior to the onset of the disease, or may have had a light infestation which was not discovered, it does suffice to definitely establish that *the disease was not associated with lousiness* This much is, indeed, sufficiently well established by the geographic and social distribution of the disease, a considerable proportion of the cases having occurred in persons of such habits and living in such an environment that the harboring of lice is not to be suspected.

DISCUSSION

The evidence thus far adduced indicates that there is endemic in the southeastern United States a disease which is as yet indistinguishable from Old World typhus, clinically and serologically, except with regard to its relatively mild clinical course and low fatality rate. It appears to be identical with the disease described by Brill as endemic in New York City. On the other hand, the epidemiological characteristics of this disease present certain points of difference with Old World typhus which appear to be significant. They relate principally to the mode of transmission.

The louse (*P. humanus* var *corporis* and *P. humanus* var. *capitis*) has been satisfactorily proven to be the usual—not necessarily the only—vector of Old World epidemic typhus. Transmission of the virus from man to man is accomplished by the agency of this insect. Reviewing the observations which have thus far been made upon the endemic typhus of the southeastern United States, consideration may

be given to the evidence for and against transmission from man to man by the louse.

As regards positive evidence which would suggest association of this disease with lice, not a single circumstance has been discovered which suggests such a mode of transmission In other words, if this disease had been considered as one of altogether unknown etiology, with no prior assumption as to its mode of transmission, the facts which have been brought out with respect to the cases observed in Alabama and Savannah, Ga , would not even give rise to the suspicion that infection was transmitted by the louse Of positive evidence tending to incriminate the louse, then, this study yields none.

Moreover, there are certain facts which weigh distinctly against the supposition that the disease, as observed in these areas, has been transmitted by lice. These are:

I. The seasonal distribution of the disease, reaching its maximum in the warm weather of summer and autumn, is the reverse of the seasonal distribution of diseases known to be louse-borne—Old World typhus, relapsing fever, trench fever, which characteristically reach their highest prevalence in the colder months of winter and spring

II. The social and environmental distribution of the disease is not such as would be expected, and in a vast majority of cases (all but 2 in a series of 197) absolutely no evidence of louse infestation was discovered It is in accordance with experience that cleanly persons upon whom lice can not establish themselves may occasionally be bitten by lice accidentally picked up, and that people of this class may consequently become infected with a louse-borne disease, especially such as are in close contact with louse-infested patients. It is, however, contrary to all experience of Old World typhus and relapsing fever, known louse-borne diseases, that infection should be almost *exclusively confined* to persons who are not demonstrably infested, as has been the case here It seems, indeed, almost inconceivable that in a louse-borne infection there should be such *absence* of association with lice.

III. As a corollary of the preceding, the lack of evidence of direct communicability, after a considerable period of observation, is not in accord with common experience in louse-borne diseases. The fact that contacts of the observed cases have rarely been infected is not by itself evidence against louse-borne infection, since these patients, being not lousy, would not be expected to spread the disease. On the other hand, it is a remarkable circumstance that the undiscovered cases which must have existed, if the disease be transmitted in this way, did not cause here and there small localized outbreaks in a labor gang, boarding house, or some equivalent group.

IV. Finally, reviewing the distribution of this disease and the circumstances existing in the communities studied, the facts seem

to be incompatible with the assumption that the infection has been conveyed by lice under the conditions which are generally accepted as governing the transmission of Old World typhus (Arkwright, 1920), based upon the present status of epidemiological and experimental evidence in that disease. These conditions may be briefly summarized as follows:

(1) That the virus exists in nature only (*a*) in the blood and tissues of infected human beings, and (*b*), in the bodies of lice which have fed upon such persons.

(2) That man is infective for the louse only for a brief period, namely, from the onset of the disease until defervescence has been established, a matter of two or three weeks.

(3) That one attack in man confers a definite, high, and durable immunity.

(4) That the louse, having bitten an infective man, after a period of five or six days is capable of conveying the infection to other persons by its bite.

(5) That the louse remains infective during the remainder of its life, a matter at most of two or three months (Nuttall, 1917).

(6) Almost all attempts to demonstrate the inheritance of infectivity in the louse have failed.[4]

To maintain the disease under these conditions of transmission, therefore, there must be available a supply of infective lice, renewed at frequent intervals by the occurrence of cases in lousy persons, either infected locally or imported. For *sustained endemic* prevalence, not tending to decline, the louse infestation of the population must be sufficient to establish on the average at least one new human infection for every one that is terminated by death or recovery. Otherwise the prevalence will decline. To meet these conditions a certain proportion of the cases, probably a majority of them, must occur in persons sufficiently infested with lice to serve as foci for the infection of others, since the cases which may occur in uninfested persons bitten casually by stray lice and living in a clean environment would not contribute to the further spread of the infection.

As to the communities considered in this study, it seems doubtful that the louse infestation of their population is sufficient to sustain an infection subject to these conditions of transmission. Obvious lousiness—heavy infestation with body lice—is an exceedingly rare

---

[4] The above are given as the conditions of transmission which seem to be generally accepted for Old World typhus. It can not be said that all these conditions have been rigidly proven. For instance the possibility has not been excluded that the virus of typhus may have some mammalian host other than man, and in fact the existence of such a reservoir is suggested by the susceptibility of certain of the lower animals to experimental infection. Nor has it been proven that the louse is the only actual or potential insect vector, or that the infection is never transmitted to the progeny of infected lice. Likewise, while there is no positive evidence of long continued infectivity of man, the possibility of occasional prolonged latent infection has not been excluded.

condition in the southern United States. The climate is mild; the winters are short; even the poorer population are relatively cleanly in person and surroundings. Lice are looked upon as a disgrace, and strenuous efforts are made to destroy them when they are found. They are occasionally encountered on beggars, vagabonds, or destitute and debilitated persons Jails, institutions caring for the poor, and cheap lodging houses sometimes become infested. No outbreaks of this disease have been traced to such places

Allan (1923), commenting upon the absence of lice in the cases which he reported, stated that in 15 years of dispensary and office practice in Charlotte, N C, he has never seen body lice on a patient. His experience in this regard is not different from that of a great many other physicians in this section of the country who have been questioned

Head lice are not so very uncommon in school children, inspections sometimes reveal as high as 4 or 5 per cent infestation in the poorer sections. In Montgomery head lice were found on a few children in three schools during 1924–25, but less than 1 per cent of the school population was affected. No relationship could be traced between these schools and the occurrence of cases.

With these observations in mind as regards the cases and the communities in which they have occurred, in order to account for the existence of a louse-borne person to person transmission in this disease in the southeastern United States one must assume the existence during at least three years of a *concealed* reservoir of infection in lousy persons, either (*a*) in the form of clinically recognizable cases which have somehow remained undiscovered by the investigation, or else (*b*) in a clinically unrecognizable form as larval cases (the "typhus exanthematique inapparent" of Charles Nicolle, 1925) or as passive carriers of the virus.

With regard to the first of these assumptions, it seems most improbable that clinically recognizable infections in louse-infested individuals should have been overlooked while such numbers of cases in vermin-free persons were discovered. Such a circumstance is the more unlikely because the cases in lousy individuals would, as has been pointed out already, give rise to household epidemics, which would attract attention.

Regarding the alternative assumption that the infection may have been spread from clinically unrecognizable cases which have occurred in lousy persons, it is undoubtedly true that mild atypical cases occur and that these may escape diagnosis, especially if the eruption is not well developed. As a result of having done a large number of Weil-Felix reactions on blood specimens from febrile cases suspected of being typhoid or typhus, it seems unlikely that abortive infections form a very appreciable proportion of the total number,

and there is no particular reason why they should be more common in the lousy than in the nonlousy.

Concerning the existence among human beings of a large number of "inapparent infections" in the sense of Nicolle, there is little evidence to support his hypothesis. Nicolle reasons that they do exist by analogy with what occurs when certain rodents are inoculated with virus in the laboratory The response of human beings to infection naturally acquired can hardly be compared with that of rodents artificially inoculated.

Human carriers of typhus virus have never been demonstrated, and from present knowledge it seems quite unlikely that they exist. The disease is apparently a blood-stream infection with localization in certain organs of the body, chiefly brain, spleen, and liver. It has been repeatedly shown experimentally that the virus disappears from the blood at the time of convalescence, or within a day or two after the temperature returns to normal. The virus has not yet been demonstrated in the discharges of the body. Upon recovery a sharp immunity is established

In order to account for the transmission of the disease from man to man by the louse under the conditions which exist in the southeastern United States, it seems necessary to assume an entirely altered conception of this disease, a conception which does not appear to be in harmony with the established facts, experimental and epidemiological, so far as they have been ascertained. In fact, whatever the means of transmission from man to man, if it be assumed that it is an exclusively human infection, then it must exist largely in unrecognized form, since it is evident that the recognized cases do not link together. These considerations have led to a tentative rejection of the human louse as the principal vector and of man as the principal reservoir of the disease in this part of the United States and the search for some other mode of transmission.

It is generally accepted that typhus—and hence the disease with which we are dealing—belongs to that group of diseases known as the "rickettsiæ." In addition to typhus, this group includes Rocky Mountain spotted fever, trench fever, Tsutsugamushi disease (including the variety described by Schuffner (1910) and by Walch and Keukenschrijver (1925) in Sumatra), and heartwater, a disease of sheep, goats, and cattle in South Africa described by Cowdry (1925). These five diseases possess certain features in common. They are acute infections transmitted by blood-feeding insects or arachnids; they exhibit a fairly high fever, running a relatively definite short course; a single attack confers upon the survivors a comparatively high degree of immunity for a period of months or years, or even for life. There is invariably more or less involvement

of the nervous system and there is a characteristic exanthem in all, with the single exception of heartwater. It seems reasonably well established that the etiologic agent of each belongs to the rickettsiæ defined by Cowdry (1925) as follows:

"Gram-negative, bacteriumlike organisms of small size, usually less than half a micron in diameter, which are found intracellularly in arthropods, which may be more or less pleomorphic and stain rather lightly with aniline dyes, but which resemble in most of their properties the type species, *R prowazeki*"

While the rickettsiæ which have been described in these diseases typically inhabit arthropod tissues, it is questionable whether an arthropod reservoir of the parasites can exist indefinitely. In Rocky Mountain spotted fever, although hereditary transmission in the tick has been demonstrated, it is not yet known through how many generations the virus can be continued in its arthropod host. Wild rodents, such as rabbits and ground squirrels, probably play a rôle in maintaining the reservoir of the virus from which man becomes infected accidentally. In Japanese river fever the vector is a mite, *T. akamushi*, found in great numbers within the ears of the field mouse (*Microtus montebelli*), which probably acts as a reservoir of the virus. Walch has brought evidence to indicate that in Sumatra *T. dehensis*, likewise a parasite of the field rat, is responsible for the transmission of the pseudotyphus of Deli Little is known of trench fever beyond its transmission from man to man by the louse In heartwater Cowdry has found that hereditary transmission of the virus in ticks does not occur, hence some other reservoir of the virus is necessary for its maintenance; presumably the sheep, goats, and cattle sick with heartwater afford this, though the possibility of a reservoir existing among small rodents has not been excluded.

In typhus fever it has been shown by Nicolle and others that beside the chimpanzee and the monkey certain small rodents are susceptible to the virus; i e, guinea pigs, rabbits, rats (white and gray), mice (white), the gerbille. In a recent publication Nicolle (1926) reports a second series of passages of typhus virus through 12 generations of white rats.

In view of these considerations the question arises whether in the endemic typhus of the southeastern United States a reservoir of the disease may not exist other than in man, a rodent reservoir with accidental transmission to man through the bite of some parasitic blood-sucking insect or arachnid. Such a hypothesis is compatible with the epidemiological characteristics which have been presented, namely, (1) the uneven focal distribution of the disease; (2) its sporadic occurrence; (3) its apparent lack of direct communicability from an infected person; (4) its association with the place of business

rather than with the home, particularly with those premises upon which foodstuffs are handled or stored; (5) the recurrence of cases on the same premises after considerable intervals of time; and (6) its seasonal incidence

Obviously the rodents upon which suspicion immediately falls are rats and mice, and the parasitic intermediaries which are first suspected are fleas, mites, or possibly ticks

Without desiring to emphasize the analogy, there is similarity between the epidemiology of this disease and that of plague as observed in the southern United States

It is interesting to note also that the observations with regard to this typhuslike disease in the southeastern United States are not peculiar to this country Many reports of a similar nature have appeared in medical literature in recent years from various parts of the world Attention is called particularly to those from Australia and from the Federated Malay States.

Hone (1922), in a series of papers, has described a situation in and around Adelaide strikingly similar to the one here reported for Savannah or Montgomery. The first 13 cases studied were in men who handled wheat, and later cases showed an apparent relationship to the handling of foodstuffs More recently Wheatland (1926) has reported a small epidemic of cases of mild typhus, giving a positive Weil-Felix, from a district surrounding Toowoomba, Australia The occurrence of these cases seemed to be associated with a migration of mice, accompanied by an epizootic, and were at first called "mouse fever"

According to Fletcher and Lesslar (1925) typhus was never recognized in the Federated Malay States until 1924 Between August, 1924, and January, 1925, a diagnosis of typhus was made in 18 cases, 7 of which were in Europeans. The disease was sporadic in occurrence; there was no evidence of the direct infection from man to man, and apparently there was an association of the disease with cattle keepers and with a camping ground that was notorious for its rats

In summary, despite the clinical, serological, and experimental evidence as to the identity of these cases in the southeastern United States with Old World typhus and "tabardillo," there are significant divergencies in the epidemiology. These lead to a tentative rejection of transmission from human to human through the louse as explaining the distribution of this endemic disease, and suggest the existence of some other mechanism for the propagation of the virus. From a consideration of what is known of this group of diseases, the "rickettsias," and specifically with regard to the susceptibility of rodents to typhus virus, it seems probable that a

reservoir may exist apart from man. A reservoir in rats or mice, with accidental transmission to man through the bite of some parasitic blood-sucking arthropod, is compatible with the epidemiological characteristics which have been revealed by this study of the disease in Alabama and Savannah, Ga Some experimental studies designed to test the theory of the existence of a rodent reservoir of the infection are now in progress in the hygienic laboratory of the Public Health Service, but have not yet progressed far enough for a report.

CONCLUSIONS

1. A disease giving a positive Weil-Felix reaction, and clinically indistinguishable from typhus fever except with regard to its relative mildness and low fatality rate is endemic in the southeastern United States.

2. The epidemiology of this disease appears to differ significantly from that of Old World typhus

3. The epidemiological characteristics afford no evidence suggesting louse transmission and are interpreted as being at variance with man-to-man transfer by lice, unless it be assumed at the same time that the disease occurs mostly in unrecognizable form.

4. It is suggested as an hypothesis which seems to afford a more probable explanation of the mode of transmission that a reservoir exists other than in man, and that this reservoir is in rodents, probably rats or mice, from which the disease is occasionally transmitted to man.[5]

ACKNOWLEDGMENTS

The author desires to express his grateful appreciation to Surg. W. H Frost for many valued suggestions in the pursuance of this study and the preparation of the manuscripts; to Dr. Samuel J. Welch, State health officer, and associates in the Alabama State Board of Health; to Dr Victor C. Bassett, city health officer of Savannah, Ga.; and to the many members of the medical profession who have generously aided in the collection of this data.

[5] This theory of the source and transmission of the "endemic typhus" referred to in this paper does not necessarily deny the identity of that disease with Old World typhus, for while it is satisfactorily proven that in its epidemic form typhus is transmitted from man to man by the agency of the louse, there remains the possibility—unsupported by positive evidence but not yet excluded—that the disease may exist also in rodents, and that in the intervals between epidemics the infection may be carried over in this reservoir.

TABLE III.—*Cases of Brill's disease occurring in Montgomery, Ala., 1922–1925*

Case No.	Race	Sex	Age	Occupation	Date of onset	Weil-Felix day after onset	Reaction result	Remarks

CHANGES IN TYPE OF CONTAGIOUS DISEASES

The above was the title given by Dr Charles V. Chapin, superintendent of health, Providence, R I, to the fourth Sedgwick Memorial lecture Doctor Chapin's lecture was printed in full in the Journal of Preventive Medicine of September, 1926. Doctor Chapin discussed especially the changes in type of contagious diseases that have occurred in smallpox and scarlet fever This lecture might well be read with profit by every health officer and sanitarian. In order to invite attention to this lecture, the following quotations therefrom are repeated:

"Forms of life well adapted to their environment survive Those ill adapted perish. It is as true of smallpox and scarlet fever germs as it is of Norway rats, or the common daisy. Any quality tending to restrict the increase in numbers of these germs, or to restrict the opportunities for transference to another host, would seem to be hostile to the maintenance of the species A germ which promptly kills its host has little time for reproduction and little opportunity for transference. If the germ puts the host to bed, even if recovery ensues, it is also inimical to the dispersion of the germ, though, in a lesser degree. The discovery of bacteria came soon after the discovery of the action of natural selection, and many bacteriologists and epidemiologists were quick to see that natural selection is hostile to the virulence of the pathogens There are some who have doubted this and have claimed that the funeral of a dead man, and the constant calls of friends at the bedside of the sick man, favor the distribution of the infecting germs, but I doubt if there is a single practicing health officer who does not feel certain that there is far less chance of a person spreading disease germs if he is dead, or in bed, than if he is going about his daily work If the diphtheria bacillus invariably put its victim to bed, there would be a very good chance that we could control the disease The reason why the diphtheria bacillus is able to maintain itself so well is because it so frequently lives in the human throat without causing symptoms sufficient to come to the attention of the health officer.

"The mild type of smallpox has by no means driven out the classical form. In many places they have existed together. Although in the United States the mild type has been the prevailing one, there has been a very respectable amount of the classical form, and nowhere has the relationship of the two been more carefully studied Practically all American health officers who have had experience with the two types believe that they are distinct and breed true. A large proportion of the classical outbreaks have been traced to foreign lands. Many others, particularly in the Southwest, were so situated that importation from Mexico was probable.

"The most important question is, Does the mild type *ever* revert to the old classical form? Many have noted the occurrence of a severe and perhaps fatal case of smallpox clearly derived from the mild strain. Rarely a second or a third case develops. I know of no certain record of an outbreak of the classical form derived from the mild in the United States. The nearest approach to such a change in type is described by Doctor Davies, of Bristol, England. He records an outbreak in Wales of 15 cases, of which 4 were confluent, and 1 of which died, which was very clearly traced to a series of typically mild cases in Bristol.

"Just how thoroughly the mild strain has become established, it would, however, be unsafe at present to say.

"That vaccinia is derived from smallpox by animal passage we know That varicella is another offshoot from smallpox is highly probable That the mild type of smallpox sometimes called alastrim, or amaas, is another cleavage seems clear. That the two strains are closely related is shown by complement fixation tests, by animal inoculation, and by the immunity against both produced by vaccinia. Nevertheless the two types differ clinically in a marked degree and to some extent in immunity relations and in animal reactions.

"The history of the appearance and dispersion of the mild type of smallpox shows that it is not to be explained by changes in the host caused by vaccination, or otherwise It is not possible that it is due to climate or any telluric, or cosmic, or mystic epidemic influence. The theory that the disease is mild because the smallpox germ has parted company with a virulent streptococcus seems highly improbable. The simple and wholly adequate theory is that in Florida or in Africa the smallpox germ some thirty years ago suddenly underwent a change, or mutation, just as many other species of plants and animals, high and low, are constantly doing."

In speaking of scarlet fever, Doctor Chapin stated:

"It was a natural suggestion that the variation in virulence shown by scarlet fever might be explained in a similar way. I have, however, found little or nothing to support this view.

"Efforts to trace the spread of either mild or severe scarlet fever from country to country, or even from one city to another, have, with very few exceptions, proved unavailing. Doubtless too much importance ought not to be attached to this, for the tracing of scarlet fever is very much more difficult than the tracing of smallpox. There may well be considerable transference of scarlet fever from place to place without our being able to discover it.

"There are, however, other reasons than inability to trace dispersion, which render it improbable that the mild type of scarlet fever is, like smallpox, derived from a sudden mutation. In the first place there do not seem to be any clearly defined types of scarlet

fever, such as we see in smallpox. I have found no instance where one type of smallpox has slowly changed to another type, although there are instances where this has been simulated, as when a severe strain was imported into Detroit during an epidemic of the mild form. With scarlet fever it is very different. The loss of virulence has nowhere been sudden Wherever scarlet fever has been growing milder the change has been gradual; for the most part very gradual A slow process of evolution seems much more probable than a sudden mutation.

"The occasional appearance of increased virulence might simply mean the occasional natural variation, or reversion, to the ancestral severe strain.

"The facts here gathered indicate, with a considerable degree of probability, that the present mild character of scarlet fever is due to the selective force of isolation eliminating the severe strains It is far from a demonstration, but it is hoped that some one will give further study to the problem, for its solution seems to me to be a matter of very great moment."

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for October, 1926

The accompanying table is taken from the Statistical Bulletin for November, 1926, published by the Metropolitan Life Insurance Co , and presents the mortality experience of the industrial insurance department of the company for October, 1926, as compared with September, 1926, October, 1925, and the year 1925.

The bulletin says:

The health situation in the industrial populations of the United States and Canada showed improvement in October as compared both with the same month of 1925 and with the preceding month of 1926 The recorded death rate (7.9 per 1,000) shares with October, 1921 and 1922, the distinction of being the lowest ever recorded for October In 1925 the rate was 8 1; in 1924, 8 5; and in 1923, 8 8.

At this season of the year special interest always attaches to what is happening with respect to influenza and the respiratory diseases This interest is somewhat accentuated at present by reports from different sections of the country which show, beyond question, that cases of influenza are increasing. Obviously, there is much concern as to the extent that this increased sickness is being reflected in the death rate. We are able to report that up to November 13 the records of the industrial department of the Metropolitan show nothing more than the expected seasonal rise in the death rate from influenza and pneumonia. Among more than 17,000,000 persons exposed to risk there were recorded, in October, 105 deaths from influenza and 740 from pneumonia. The death rate in October for these two diseases combined was 55.6 per 100,000. This actually shows improvement over October of last year, when the rate was 60.1. Furthermore, in both the first and second weeks of November the combined mortality from influenza and pneumonia was lower than in the corresponding weeks of 1925,

at a time when no particular anxiety was being manifested about any impending outbreak of influenza Current low rates for heart disease, Bright's disease, and cerebral hemorrhage also indicate that the kind of influenza now prevailing is not the virulent type

The mortality from each of the principal epidemic diseases of childhood is low, although the diphtheria death rate rose rather sharply from 6 5 per 100,000 in September to 10 5 in October, in October a year ago it was 9 7 Tuberculosis, diarrheal diseases, and puerperal conditions show improvement over October, 1925.

In the field of deaths due to violence, suicides continue to be reported in unusual numbers, and if there is no slackening during November and December in the suicide rate the figure recorded for the year 1926 will be higher than for any year since 1921, it may even exceed the rate for that year, in which event it will be the highest recorded since 1917 The homicide rate, in October, was a little lower than in September, and in October, 1925 Automobile fatalities were fewer than in October, 1925

Death rates (annual basis) for principal causes per 100,000 lives exposed, September and October, 1926, October, 1925, and year 1925

[Industrial department, Metropolitan Life Insurance Co]

Causes of death	Rate per 100,000 lives exposed [1]			
	October, 1926	September, 1926	October, 1925	Year 1925

PUBLIC HEALTH ENGINEERING ABSTRACTS

A Note on the Rearing of Anopheline Larvæ. Mark F. Boyd. *Bulletin of Entomological Research*, vol. 16, part 4, March, 1926, p. 308. (Abstract by L. D. Fricks.)

This article describes a successful method of rearing adult Anopheles from eggs deposited by captive females. The author states that the chief difficulty in rearing Anopheles in the laboratory arises from a lack of vitamines in their algæ food. He overcomes this

difficulty by feeding Fleischmann's Yeast and by this method of feeding attained a high degree of success, 100 per cent development from eggs to adults in 13 days

A small amount of yeast was daily rubbed into the superficial layer of water in the culture pans Marble dust was kept in the pans to conserve alkalinity, and the water was changed frequently.

The Mosquitoes of the Lower Fraser Valley, British Columbia, and their Control. Eric Hearle, B Sc. Report No 17, Canadian National Research Council, Ottawa, 1926 91 pages. (Abstract by W. H W. Komp)

A very complete study of the mosquitoes of the region, with keys to the species found, illustrations of the most common species, observations on the breeding habits, and excellent photographs of typical breeding places, including some fine airplane views. The lower Fraser Valley is the richest agricultural area in British Columbia, small-fruit growing, livestock breeding and dairying, and lumbering being the principal industries The lower valley is flat, interlaced with numerous slow, winding creeks and sloughs During the greater part of the year the river is at low stage, but during the late spring and early summer freshets from melting snow flood the lowlands, causing extensive temporary swamps. These give rise to a mosquito pest that seriously interferes with the proper development of the country. At high water about 14,000 acres are affected. The report recommends as a temporary measure the use of oil and of oil-soaked sawdust for small areas, and the diking and draining of the larger areas. Stress is laid on the necessity for cooperation among the various political divisions in financing these projects. Evidence of the migration of mosquitoes for 10 to 15 miles from their breeding grounds has been found; these nullify the best-intentioned local operations, and make it imperative that some central board direct the mosquito-control measures.

The Effect of Turbulent Air Motion and of Humidity on the Stability of Dust, Fumes, and Smoke Clouds. Philip Drinker, R. M. Thomson, and Jane L. Finn *The Journal of Industrial Hygiene,* vol. 8, No 7, July, 1926, pp. 307–313. (Abstract by Leonard Greenburg.)

In this very interesting contribution Mr. Drinker and his associates report on a series of studies made in the gassing chamber at the Harvard School of Public Health. In these studies suspensions of dusts of various kinds (silica, zinc oxide, and tobacco smoke) were set up and the rate of sedimentation curve was determined by means of a Tyndall meter attached to one side of the chamber. The influence of air motion was found by determining the change in the sedimentation curve affected by the use of electric fans, and the effect of moisture was found by the changes produced in the shape of the

curve when steam was blown into the chamber. In some cases the humidity of the cabinet was raised to the saturation point by blowing steam into the chamber, then slowly allowing the saturation to fall to 95 per cent prior to the introduction of the dust

As a result of these studies turbulent air motion was found to have no effect on the subsidence of silica dust but a marked effect on zinc oxide and a considerable effect on tobacco smoke Local humidification has a marked effect on silica dust and on zinc oxide. General humidification of the cabinet failed to affect the settling rate of silica dust and tobacco smoke but hastened the settlement of zinc oxide both as a powder and as a fume.

How to Get a Smokeless Atmosphere and Make it Pay. Councillor W Brownhill Smith *The Journal of State Medicine,* vol 34, No 7, July, 1926, pp 422–427 (Abstract by Leonard Greenburg)

In this paper the author points out that smoke exerts a harmful effect on health either directly by affecting the organs of respiration or indirectly by cutting down the normal quantity of sunshine which is now known to be so essential to health According to the 1920 Report of the Departmental Committee on Smoke and Noxious Vapors Abatement, "the number of deaths from pulmonary and cardiac diseases is shown to increase in direct proportion to an increase in the intensity and duration of smoke fogs" In the cities of Great Britain particularly, and to a large extent in the rural districts, the effect of fog is generally admitted to be a pernicious one.

The fog of the cities of Great Britain is in a large measure due to the use of coal in individual grates for heating purposes, central heating being employed only to a very minor degree.

The duty of the medical men is to preach against the evils of the smoke-laden atmosphere, according to the author of this paper.

The use of gas affords a method of heating and cooking which is free of smoke production, and in those areas of the country where gas is relatively cheap this method should find wide favor And according to the author, Prof. Parker Smith, of Glasgow, has shown that in certain large towns where electricity is supplied at a low price it is cheaper to heat cottages and villas by this means than with coal. But for the majority of towns (where these conditions do not obtain) it is necessary to resort to other means in order to keep the atmosphere smoke free. This can only be done by the provision of a smokeless fuel that can not burn in the types of grates and cookers now in use.

The writer then reviews the steps taken by the Glasgow Gas Committee in its search for a fuel which would burn satisfactorily in ordinary domestic grates.

Experimentally, small-size plants and finally large-size plants were constructed, using the process of Robert Maclaurin for coal carboni-

zation, all of which have come to a very satisfactory termination The carbonized fuel known as "Kincole" has 45 per cent more heating power than an equal weight of raw coal and burns smokelessly in the ordinary domestic grate. By this method a highly satisfactory smokeless fuel is obtained and the cost of gas manufacture is at the same time lowered The author urges the use of this smokeless fuel.

Do Water Supplies Disfigure Teeth of Children? (Comments in response to an article entitled "Water Supplies Charged with Disfiguring Teeth" which appeared in *Water Works Engineering* January 15, 1926). *Water Works Engineering*, vol. 79, No. 15, August 1, 1926, p. 995. (Abstract by Frank Raab.)

Richard Messer, Richmond, Va., quoted several dentists, some of whom blame the trouble of mottled enamel to water. Another, who is himself affected, does not blame it to the water According to Doctor McKay, there are two localities on the Atlantic seaboard where the trouble of mottled enamel appears, and in each case it is blamed to artesian water.

M. H McCrady, of Montreal, Canada, writes that the trouble of mottled enamel is new in his experience, but admits that it might exist in some parts of the country, H. E Moses, Harrisburg, Pa., believes that the above trouble is found very rarely in Pennsylvania. He offers no suggestion as to the cause

Raising the Standard of Water Supplies. A. L Dopmeyer, Associate Sanitary Engineer, United States Public Health Service. Proceedings of Eighth Texas Water Works Short School, January 18–23, 1926, pp. 18–22. (Abstract by V. M. Ellers)

In this paper a plea is made for a sanitary engineering organization representing the State, with adequate personnel and appropriations to give the advice and assistance to communities on sanitary engineering problems, which they need and have a right to expect.

Many communities which do not as yet realize the value of a water supply of high sanitary quality should be properly educated by engineers representing the State, according to the author, and the raising of the general standard of water supplies in the State is said to be dependent on such education.

The routine activities recommended by the Conference of State Sanitary Engineers for effective control of water supplies by State health departments are set forth as an indication of the magnitude of the work involved in this task alone, which is but one of the manifold duties a State sanitary engineer is expected to perform.

The development of State supervision and control over water supplies is also briefly outlined in this paper, depicting the active part which the United States Public Health Service has played in organizing and developing State sanitary engineering divisions.

Some Aspects of the Housing Problem. C A Clews *Journal of the Royal Sanitary Institute*, Vol 46, No 12, May, 1926, pp 581–583. (Abstract by R E Tarbett)

This article covers the problem of providing housing accommodations in Derby since the war Under the 1919 act the corporation built 724 houses at a cost of 20s 6d. to 22s 8d per super foot for the parlor type, and 18s 2d to 20s for the nonparlor type Construction material is not given

Under the 1923–24 act the corporation is building 1,850 houses. Brickwork was found to be the cheapest form of construction. The cost of these houses of the nonparlor type with three bedrooms is £461 10s or 11s 3d and of the same type with two bedrooms £339 or 10s per super foot of floor space, exclusive of land and street works. The parlor type with three bedrooms cost £530 or 11s 2d. The greater part of the houses are semidetached and built with a density of 12 per acre.

As building was not progressing rapidly enough, it was decided to erect 250 cast-iron houses These houses cost about the same as the other type but could be quickly erected and would not draw on the skilled labor already employed A detailed description of these houses is given These houses appear comparable with the small five-room house in the United States, having two floors with three bedrooms and bath on the upper floor The foundations are of concrete carried 6 inches above ground. The outer walls are of cast plates 3 feet square and 3/8 inch thick with flanges 2⅝ inches wide. The plates are covered with special cement and the flanges are slightly recessed to allow for a nailing strip. Studding 2 by 3 inches is used, and walls are lined with asbestos sheeting. Roof is of timber, covered with tile; windows and door casings of wood; floor of living and bedrooms of wood and of other rooms concrete. Houses are equipped with grate and back boiler, hot and cold water, and electricity. A few other types of houses have been built. Rent for the nonparlor, three-bedroom type of house is 12s 3d. per week, and for the two-bedroom 10s per week.

The writer concludes that in view of the still serious shortage the aim should be to construct as cheaply as possible, without sacrifice of health or durability, a type which may be erected quickly and the rental of which would come within reach of the ordinary artisan, say not more than one-sixth of his income.

Automobiles and Public Health. W. J McConnell, Medical Secretary, Philadelphia Health Council and Tuberculosis Committee. *American Public Health Journal*, vol. 16, No. 9, September, 1926, pp. 884–886. (Abstract by H. N. Old.)

There is mentioned in this article the possible factor of accidents and the industrial hazard in the manufacture and addition of certain compounds tending to increase the efficiency of motor fuels, but the greater part is devoted to the hazard of carbon-monoxide poisoning resulting from combustion of the fuels.

The danger by reason of a running motor in a closed or a poorly ventilated inclosure is referred to at some length, but more space is devoted to the subject of excessive concentration of CO in the atmosphere of localities where motor-car traffic is heavy or in tunnels and similar covered passageways subjected to exhaust gas, 7 per cent of which is said to be carbon monoxide, while an atmosphere containing 1 per cent is known to be sufficient to cause death in a very short time.

Reference is made to the research work in connection with the Hudson tubes, which lead to a permissible maximum CO concentration of 4 parts per 10,000 for a period of an hour, determinations being on basis of physiological tests. It is stated that other workers have found frequently 0.01 per cent in the atmosphere of parts of Fifth Avenue, New York City, and state that 0.02 per cent and even more was not unusual in limited areas and for short periods. This concentration is not considered serious.

Brief reference is also made to some of the symptoms of carbon-monoxide poisoning and to emergency treatment. Methods and apparatus for CO determinations are discussed very briefly, but a list of related publications for reference purposes is included.

DEATHS DURING WEEK ENDED DECEMBER 11, 1926

Summary of information received by telegraph from industrial insurance companies for week ended December 11, 1926, and corresponding week of 1925 (From the Weekly Health Index, December 16, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Dec 11, 1926	Corresponding week, 1925
Policies in force	66,332,374	62,333,156

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended December 4, 1926, 41 States reported 2,525 cases of diphtheria For the week ended December 5, 1925, the same States reported 2,295 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,000,000, reported 1,299 cases of diphtheria for the week ended December, 4, 1926. Last year for the corresponding week they reported 942 cases. The estimated expectancy for these cities was 1,376 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles—Thirty-eight States reported 5,178 cases of measles for the week ended December 4, 1926, and 4,443 cases of this disease for the week ended December 5, 1925. One hundred cities reported 1,021 cases of measles for the week this year and 1,963 cases last year

Poliomyelitis—The health officers of 42 States reported 34 cases of poliomyelitis for the week ended December 4, 1926 The same States reported 37 cases for the week ended December 5, 1925

Scarlet fever—Scarlet fever was reported for the week as follows: Forty-one States—this year, 4,038 cases. last year, 3,704 cases; 100 cities—this year, 1,392 cases; last year, 1,199 cases; estimated expectancy, 1,031 cases.

Smallpox—For the week ended December 4, 1926, 41 States reported 612 cases of smallpox Last year for the corresponding week they reported 433 cases One hundred cities reported smallpox for the week as follows: 1926, 83 cases; 1925, 73 cases; estimated expectancy, 55 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever—Five hundred and thirty-seven cases of typhoid fever were reported for the week ended December 4, 1926, by 41 States For the corresponding week of 1925 the same States reported 667 cases of this disease. One hundred cities reported 60 cases of typhoid fever for the week this year and 110 cases for the corresponding week last year. The estimated expectancy for these cities was 86 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,350,000, as follows: 1926, 771 deaths, 1925, 860 deaths.

19530°—26——4

City reports for week ended December 4, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported

[1] Typhus fever; 1 case at Baltimore, Md.

[2] Dengue; 1 case at Charleston, S. C.

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended December 4, 1926, compared with those for a like period ended December 5, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, October 31 to December 4, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Arabia —Aden, Jeddah, Kamaran, Perim

Iraq —Basrah

Persia —Mohammerah, Bender-Abbas, Bushire

British India —Karachi, Chittagong, Cochin, Negapatam

Portuguese Indies —Nova Goa

Federated Malay States —Port Swettenham

Straits Settlements —Penang

Dutch East Indies —Smarang, Batavia, Surabaya, Sabang, Makassar, Banjermasin, Palembang, Belawan-Deli, Padang, Tarakan, Menado Balikpapan.

French Indo China —Saigon and Cholon

Sarawak —Kuching

British North Borneo —Sandakan, Jesselton, Kudat, Tawao

Portuguese Timor —Dilly

China —Amoy Shanghai (International Settlement)

Hong-Kong

Macao

Formosa —Keelung

Japan —Yokohama, Osaka, Nagasaki, Niigata, Tsuruga, Hakodate, Shimonoseki, Moji Kobe

Korea —Chemulpo

Manchuria —Mukden, Changchun, Harbin, Antung, Yingkow

Kwantung—Port Arthur.

U S S R —Vladivostok.

AUSTRALASIA AND OCEANIA

Australia —Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island

New Guinea —Port Moresby

New Britain Mandated Territory —Rabaul and Kokopo

New Zealand —Auckland, Wellington, Christchurch, Invercargill, Dunedin.

New Caledonia —Noumea

Fiji —Suva

Hawaii —Honolulu

Society Islands —Papeete

AFRICA

Egypt —Port Said, Suez.

Anglo-Egyptian Sudan —Port Sudan, Suakin

Eritrea —Massaua

French Somaliland —Jibuti.

British Somaliland —Berbera

Italian Somaliland —Mogadiscio

Kenya.—Mombasa

Zanzibar.—Zanzibar

Tanganyika —Dar-es-Salaam

Seychelles —Victoria.

Madagascar —Majunga, Tamatave

Portuguese East Africa —Mozambique, Beira, Lourenço-Marques.

Union of South Africa —East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

Dutch East Indias.—Samarinda, Pontianak.
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.

ARGENTINA

Plague—Province of Cordoba—November 20, 1926.—Under date of November 20, 1926, five cases of plague were reported at localities in the interior of the Province of Cordoba, Argentina. The cases were mild and have not been bacteriologically verified.

BRAZIL

Mortality—Communicable diseases—Santos—August 29–October 3, 1926.—During the six-week period ended October 3, 1926, 255 deaths from all causes were reported at Santos, Brazil, the greatest number of deaths reported during one week being 59 and the lowest 35. The deaths included influenza, 4; malaria, 4; measles, 8; puerperal fever, 2, tetanus, 3, tuberculosis, 42, typhoid fever, 4; whooping cough, 1. During the period under report dysentery was stated to have been present. Population, 150,000.

CANADA

Communicable diseases—Week ended November 27, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended November 27, 1926, as follows:

Diseases	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	22							22
Poliomyelitis				2				2
Smallpox				34	2	21	4	61
Typhoid fever			3	10	2	14	3	32

CHINA

Communicable diseases—Canton—September, 1926.—During the month of September, 1926, communicable diseases were reported in Canton, China, as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Cholera	72	32	Measles	2	
Diphtheria	1		Smallpox	1	
Dysentery	10	4	Typhoid fever	28	2
Influenza	14				

Population, 1,300,000.

EGYPT

Plague—November 5–11, 1926.—During the week ended November 11, 1926, a case of plague was reported in Egypt, occurring in the district of Tanta.

Summary.—During the period January 1 to November 11, 1926, 142 cases of plague were reported in Egypt, as compared with 136 cases during the corresponding period of the year 1925.

GERMANY

Further relative to typhoid fever epidemic—Hanover.—Information dated November 22, 1926, shows that the epidemic of typhoid fever which was reported at Hanover, Germany, September 18, 1926, with a total of 1,504 cases under treatment and 42 fatalities to that date,[1] was considered terminated, only a few cases being reported at that time. The highest point of prevalence was reached with 2,000 cases under treatment. The total number of deaths reported was 267.

JAMAICA

Smallpox (alastrim)—October 31–November 27, 1926.—During the period October 31 to November 27, 1926, 20 cases of smallpox, reported as alastrim, were notified in the Island of Jamaica, occurring at localities outside of Kingston.

Other communicable diseases.—During the same period other communicable diseases were reported in the Island of Jamaica as follows:

Disease	Cases: Kingston	Cases: Other localities	Disease	Cases: Kingston	Cases: Other localities
Cerebrospinal meningitis		2	Puerperal fever		1
Chicken pox		5	Tuberculosis (pulmonary)	7	29
Dysentery	5	117	Typhoid fever	18	99

Population: Island, 916,620; Kingston, 62,707.

MADAGASCAR

Plague—September 16–30, 1926.—During the period September 16 to 30, 1926, 98 cases of plague with 93 deaths were reported in the island of Madagascar. The occurrence was distributed according to Provinces as follows: *Itasy*—Cases, 1; deaths, 1; *Majunga*—cases, 9; deaths, 8; *Moramanga*—cases, 23; deaths, 23; *Tananarive* (town)—cases, 4; deaths, 3, other places in Tananarive Province—cases, 58; deaths, 55. The distribution of occurrence according to type was: Bubonic—cases, 44; deaths, 41; pneumonic—cases, 32, deaths, 30; septicemic—cases, 22; deaths, 22.

[1] Public Health Reports, Oct. 29, 1926, page 2511.

PERU

Mortality from certain diseases—September–October, 1926.—Arequipa.—During the months of September and October, 1926, deaths from communicable diseases were reported at Arequipa, Peru, as follows: *September, 1926*—Gastroenteritis, 1 death; influenza with complications, 13 deaths; tuberculosis, 14; typhoid fever, 2. *October, 1926*—Gastroenteritis, 7, influenza, 8, tuberculosis, 19. Population, 43,000.

Disease prevalence.—Gastroenteritis in children, smallpox, tuberculosis, typhoid fever, and in winter bronchial affections and pneumonia, were stated to be the prevailing diseases at Arequipa.

Plague—October, 1926.—During the month of October, 1926, 36 cases of plague with 13 deaths were reported in Peru, occurring in the departments of Lambayeque, Libertad, Lima, and Piura. In the department of Cajamarca plague was reported present in one Province and locality, with an unreported number of cases. (See p. 3031.)

SENEGAL

Plague—Yellow fever—November 1–10, 1926.—During the period November 1 to 10, 1926, 55 cases of bubonic plague, with 27 deaths, occurring in natives, were reported from the interior of Senegal, West Africa. Five deaths from yellow fever, of which three were in Syrians and two in Europeans, were reported from the Kaolak region, Senegal.

Measures to prevent spread.—The infected areas were stated to have been isolated and measures taken to localize the outbreaks and prevent spread.

UNION OF SOUTH AFRICA

Plague—Cape Province—October 24–30, 1926.—During the week ended October 30, 1926, a fatal case of plague, occurring in a European, was reported in the Williston district, Cape Province, Union of South Africa. The case occurred on a farm, and the patient was in direct contact with and had helped to nurse the previously reported cases, who were members of his family.

Smallpox.—During the period under report outbreaks of smallpox were reported in the Cape Province, occurring in two districts. In Natal two new cases were reported in Inanda district, in Hindus, both contacts with previous cases removed from Shire's barracks, Durban. Twenty-two further cases were reported in Durban, making a total from date of original outbreak at Durban, week ended October 16, 1926, of 38 cases, with 8 deaths, occurring in Hindus.

Measures to prevent spread.—Isolation of all cases and suspects in hospital; surveillance of all contacts; vaccination or revaccination of the population in and around Durban.

Typhus fever—Cape Province—Orange Free State—September, 1926.—During the month of September, 1926, 48 cases of typhus fever with two deaths were reported in the Union of South Africa The occurrence was distributed as follows: *Cape Province*—Cases, 24, deaths, 2 *Orange Free State*—Cases, 24 The occurrence was in the colored or native population

YUGOSLAVIA

Communicable diseases—October, 1926—During the month of October, 1926, communicable diseases were reported in Yugoslavia as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Anthrax	66	13	Rabies	2	2
Cerebrospinal meningitis	7	2	Scarlet fever	334	74
Diphtheria	237	41	Tetanus	30	11

PREVALENCE OF DISEASE

PUBLIC HEALTH REPORTS

VOL. 41 | DECEMBER 31, 1926 | NO. 53

CURRENT WORLD PREVALENCE OF DISEASE

A REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED OCTOBER 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT[1]

Only five of the ports in the Far East, which report to the Singapore Bureau, reported either cases of cholera or deaths from this disease during the two weeks ending October 9, and in nearly all localities in eastern Asia, where cholera was prevalent during the past summer, there was marked improvement in the situation at the end of August or during September according to the data made available in the October Epidemiological Report published by the Health Section of the League of Nations. The table below gives the reports from port towns for the five weeks ending October 9.

TABLE 1.—*Cholera cases reported in the principal maritime towns of the Far East between September 5 and October 9, 1926*

Towns	Weeks ending—				
	September			October	
	11	18	25	2	9
Deaths					
Calcutta	18	9	7	------	14
Madras	0	1	3	0	0
Vizagapatam	1	3	0	0	0
Cases					
Bangkok	7	2	3	0	2
Amoy	53	50	42	23	18
Shanghai	57	66	31	22	6
Antung	0	0	0	2	0
Dairen	3	1	1	0	0
Harbin	27	------	0	0	0

At Shanghai and Amoy a marked diminution in the number of new cases of cholera was shown by the reports for the two weeks ending October 9, and the outbreaks at Harbin and Dairen apparently had come to an end. In southern China, at Hoihow, Hainan, the number of deaths from cholera declined from 410 in the four weeks ending August 1 to 116 in the five weeks ending September 5. Cholera was reported also from Swatow and other parts of the island of Hainan. At Kwang-Chow-Wan, where 483 cholera cases were reported in August, 194 cases were reported from September 1 to 20.

[1] From the Office of Statistical Investigations

"Cholera remained prevalent in Tonkin and Annam in September but disappeared from the remainder of French Indo-China except for a few sporadic cases," says the Report. Cases reported in each Province from June to September are shown in the table below.

TABLE 2.—*Cholera cases reported in French Indo-China, June–September, 1926*

Month	Cambodia	Cochin-China	Laos	Annam	Tonkin
June	521	1,159	0	128	724
July	362	403	7	212	784
August	120	39	32	297	234
September	4	5	0	138	200

The incidence of cholera in Siam has been declining since last May when 2,660 cases were reported. During the four weeks ending September 11, 204 cases were reported as against 674 cases in the previous four weeks

Plague.—Three cases of plague were reported at Constantinople during September and none in other Mediterranean ports during the month Twelve cases occurred in the western desert district of Egypt at Sidi-Barrani between August 19 and September 4, but no cases were reported from any part of Egypt during the remainder of September.

At Beirut, Syria, there were 2 cases of plague on October 11 and another on October 12.

A marked decrease in plague occurred in Senegal during August when only 37 new cases were notified as against 178 in July and 192 in June, the peak month of the outbreak

In Madagascar the number of cases showed an increase during August, and more cases were reported than in August of any previous year. "The disease is, as usual, most prevalent in the Province of Tananarive," states the Report, "but is spreading also elsewhere and especially at Majunga, where 42 cases were reported during the first half of September. Pulmonary and septicemic cases were very common, as is seen from the table below."

TABLE 3.—*Plague cases reported in Madagascar, showing type of disease, July 16 to September 15, 1926*

Date	Bubonic	Pulmonary	Septicemic	Total
July 16-31	2	5	0	7
Aug. 1-15	21	7	2	30
Aug. 16-31	42	32	38	112
Sept 1-15	58	17	12	87

"In India plague was spreading during August in Lower Burma and in the Central Provinces and Berar. Outside of these two areas only a few plague cases were reported. In the ports plague cases were reported in September at Rangoon and at Bombay."

No case of plague was reported in August or September at Kwang-Chow-Wan, where 52 cases occurred in June and July. In French Indo-China there were 3 plague cases in September as against 11 in August Siam reported 6 plague cases in August and only 1 in July.

Plague incidence in Java during the past summer reached the lowest level since 1919. The table below shows that the improvement was general throughout the island with the exception of the Province of Pekalongan, where plague was not very prevalent in 1925 In Surakarta, which was the worst infected Province, a remarkable decline is shown.

TABLE 4.—*Plague deaths reported in Java between June 21 and August 14, 1925 and 1926*

Provinces	1925	1926
Bantam, Batavia, and Preanger	0	0
Cheribon	122	42
Pekalongan	94	150
Semarang	39	1
Banjumas	182	32
Kedu	167	55
Djokjakarta	13	36
Surakarta	631	38
East Java and Madura	8	1
Total	1,256	355

Twenty-one plague cases were reported in Peru in August, nearly all in the Department of Lima. Seven cases were reported at Guayaquil, Ecuador, in the same month. Argentina reported 3 cases in the first week of October, all in inland localities of the Provinces of Cordoba and Chubut.

Yellow fever.—Cases of yellow fever reported were as follows:

TABLE 5.—*Yellow fever*

Localities	Date	Cases	Deaths
Africa:			
Dahomey—			
Porto-Novo	Sept. 10	2	1
Gold Coast	July 1-31	8	3

	June 20-26	2	1
	July 4-10	1	

[1] Public Health Reports

In the Gold Coast 17 cases had been reported from March to July, more than during either of the previous two years, when 6 and 8 cases were reported in 1924 and 1925, respectively.

Typhus and relapsing fever—Typhus reaches its minimum seasonal incidence in Europe in the late summer, and the disease was little in evidence during August and September. A slight recrudescence

in Poland occurred in September, when 55 cases were reported during the two weeks ending September 18 as against 15 in the previous two weeks.

In Korea, where 118 cases of typhus were reported in June, the incidence declined markedly and only 37 cases were reported in July. No cases have been reported in Japan since May

Typhus has shown a declining incidence in Chile since 1920, and its decline was accelerated during the first half of 1926, when 83 cases were reported, compared with 317 during the corresponding period of 1925.

An outbreak of relapsing fever occurred in Nigeria in June and July and 324 cases with 41 deaths were reported.

Smallpox.—"Smallpox is becoming increasingly rare on the European Continent," says the Report, but "A new increase of smallpox began early in September in England; 443 cases were reported during the four weeks ended October 2, as against 305 cases during the previous four weeks and 119 during the corresponding period last year. The great majority of cases occur, as usual, in northern England, but there have been a few cases also in London and in Middlesex. There was 1 death from smallpox at South Shields and 1 in the suburbs of London during the week ended October 2."

Dysentery.—The usual seasonal rise in the incidence of dysentery occurred in August or September in most of the central European countries. In Germany 887 cases were reported in the four weeks ending September 18 as against 565 in the previous four weeks, but the incidence was no higher than in either of the previous two years. Czechoslovakia reported 206 cases, Hungary 426 cases, and the Kingdom of the Serbs, Croats, and Slovenes 236 cases in August. In Poland 1,310 cases were reported during the four weeks ended September 18, an increase over the 849 cases in the corresponding period of 1925, but not much more than 50 per cent of the 2,303 cases reported in the corresponding weeks of 1924.

In Japan dysentery shows the same seasonal variation common in Europe, and this year the disease has been more prevalent than it was in 1925 In Java bacillary dysentery was reported to be very prevalent in the first quarter of the year, but the incidence subsided during the spring. There were a number of local outbreaks in scattered districts of the island and no general epidemic.

TABLE 6.—*Dysentery cases reported in Japan and Java by four-weekly periods, 1924, 1925, and 1926*

Jan 2	243	302	-------	353	648	-------

[1] Bacillary dysentery only. [2] Data for calendar months. [3] Data for period June 1-20.

Enteric fever.—The report states: "The incidence of enteric fever in European countries in August did not on the whole differ greatly from last year. The situation was more favorable than in August, 1925, in Denmark, Norway, Great Britain, and the Balkan countries. More cases were reported in Poland in August and September than during the corresponding months of 1925. A sudden and severe outbreak of enteric fever occurred in September at Hanover, in Germany, where over 2,000 cases were reported in three weeks. During the two weeks ended September 25, 111 deaths were attributed to enteric fever in the city of Hanover alone. During the week ended August 28 also, 100 cases of 'meat poisoning' were reported at Hanover. The Deutsche Medizinische Wochenschrift states that during that week numerous cases of infectious enteritis occurred at Hanover and were ascribed to the unusually high bacterial content of the drinking water. The bacilli disappeared after chlorination of the water."

In Palestine 421 cases of enteric fever were reported during June and July, compared with 147 cases during the corresponding two months of 1925.

In the United States the incidence was slightly lower than last year. During the four weeks ended September 4, 38 States reported 4,849 cases.

Influenza.—In Mauritius 910 influenza cases and 35 deaths were reported in June; the seasonal maximum is usually in July. Mild outbreaks were reported in July in Basutoland and southern Rhodesia.

New Zealand reported an outbreak of influenza which started in June and reached its maximum in July. During the 12 weeks ending September 6, 117 deaths were attributed to influenza as against 7 during the corresponding period last year.

Acute poliomyelitis—"An unusual prevalence of poliomyelitis was reported in England and Wales, where more cases were notified in August and September than during the corresponding months of any of the previous eight years," says the Report. The highest number of cases was reported in the county of Leicester, where there were 102 cases during the eight weeks ending October 9, and in Essex, where there were 52 cases in the same period.

An extensive outbreak also occurred in Germany, where it seems to have reached its maximum in the first weeks of September. The cases were scattered throughout northern Germany, while Bavaria, Wurtemberg, and Baden were practically free from the disease

TABLE 7.—*Cases of poliomyelitis notified in England and Wales and in Germany in 1925 and 1926*

Four weeks ending—	England and Wales		Germany	
	1925	1926	1925	1926

Oct. 10	57	227	53	
Nov. 7	44		45	
Dec. 5	28		37	

Poliomyelitis was much less prevalent in August in the United States than during the previous two years. The disease was also less prevalent in the Scandinavian countries.

Scarlet fever.—Scarlet-fever cases increased in Germany, the Netherlands, and especially in Poland during August and September, and in all three countries the incidence is higher than last year.

TABLE 8.—*Scarlet-fever cases reported in Poland, Germany, and the Netherlands, July 18–October 9, 1925 and 1926*

3 weeks ending—	Poland		Germany		Netherlands

In Poland scarlet fever was reported to be most prevalent in the populous centers and the highest incidence to be among the Jewish population. At Warsaw 14,000 children had been vaccinated against scarlet fever and only 2 cases out of 410 cases reported occurred among those previously vaccinated.

In Germany the disease is most prevalent in east Prussia, Brandenburg, Silesia, Saxony, and the Rhineland; least prevalent in Bavaria and Wurttemberg

Diphtheria.—The incidence of diphtheria in Europe, on the whole, was slightly lower in August and the first half of September than it was last year. A slight increase over last year, however, was indicated in the reports for Poland, Hungary, Kingdom of the Serbs, Croats, and Slovenes, and Bulgaria

In the United States about the same number of diphtheria cases were reported early in September as at the corresponding date last year

Tuberculosis.—The mortality from tuberculosis in a number of large towns during the first half of 1926 is compared with the corresponding rates for 1925 in the following table While the mortality from tuberculosis is usually higher in the first half year than in the second half year, and these rates, therefore, are not representative of the annual rate, they show, nevertheless, that the decline in tuberculosis mortality has continued in nearly all the towns.

SYNTHESIS AND INDICATOR PROPERTIES OF SOME NEW SULFONPHTHALEINS

By BARNETT COHEN, Chemist, Hygienic Laboratory, United States Public Health Service

Sensitiveness, brilliant color, and general stability place the simpler sulfonphthaleins in the front rank of acid-base indicators. Although a few of these compounds have been known for some time, a fuller realization and utilization of their unique properties as indicators did not appear until Lubs and Clark (1915, 1916) reported some new syntheses, and Clark and Lubs (1916) proposed their selection of indicators for the determination of hydrions. Not only was a useful set of indicators presented by these authors but, as will be shown presently, there was implicit in their data the means for extending and modifying the series almost at pleasure Indeed, given the requisite skill in organic synthesis, it would be no great exaggeration to claim the possibility of producing a sulfonphthalein of any desired apparent dissociation constant (useful indicator range) and of almost any color characteristics, within limitations.

The writer's attention was drawn to the problem specifically by the need for a sulfonphthalein substitute for methyl red (an azo compound) in the Clark and Lubs series Hydrion color standards containing methyl red are notoriously unstable, and the indicator becomes unreliable when used in a biologically active medium, owing, presumably, to more or less reversible reduction and to decompositions. By comparison, the sulfonphthaleins as a class are much more stable. Hence the development of a sulfonphthalein substitute for methyl red would serve two useful purposes—(1) eliminate the unreliable methyl red and (2) render the Clark and Lubs series more uniform chemically.

Analysis of the data of Clark and Lubs led to the decision that di-halogenation of a meta-methyl phenol should produce the desired substitute, and experimental test resulting in the synthesis of tetra-brom-m-cresol sulfonphthalein (brom cresol green) verified this conclusion. Incidentally, a number of other compounds were prepared; and six of them appeared of sufficient value as indicators to merit further study and introduction into the Clark and Lubs series.[1]

The following report includes a description of the synthesis of the new sulfonphthaleins and of their absorption curves in the visible spectrum. The apparent dissociation constants were also determined, and data are presented on the salt and protein errors.

---

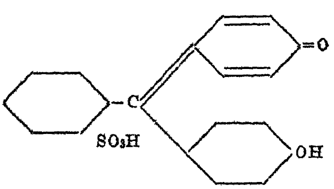
[1] A preliminary report on five of these compounds was made in 1923. Public Health Reports, 38, 199. Circumstances have prevented a more detailed report until now, but in the meantime the essential details for the synthesis of these compounds were made available to all inquirers.

EFFECTS OF SIMPLE SUBSTITUTIONS IN PHENOLSULFONPHTHALEIN UPON IONIZATIONS

Structurally phenolsulfonphthalein is a triphenylmethane derivative containing a sulfophenyl and two phenol radicals, the latter attached in their para positions to the methane carbon.

Rather little is known of the effects of substitution in the sulfophenyl radical upon dissociations in the compound (cf. Lubs and Acree, 1916) The dissociation in the strong sulfonic acid radical occurs in the extreme acid ranges, and theoretical considerations suggest that pronounced changes in the constant of this dissociation should be produced by substitutions in the sulfobenzoic acid nucleus. Consequently, should the need arise for the development of sulfonphthalein indicators for extremely acid regions, this type of substitution would be likely to yield compounds of the required indicator properties.

Although accurate comparative measurements of dissociation constants of the sulfonic acid in the different known sulfonphthaleins are not available, we do know that alkyl substitution in the position meta to the phenolic hydroxyl (such as is found in thymol sulfon-



phthalein and m-cresol sulfonphthalein) suppresses this dissociation greatly, enough at least to enable the employment of these compounds as indicators in the pH region between 1.0 and 3.0.

More useful and definite data are available as to the effects of substitution in the phenolic radicals upon the dissociation of the phenolic hydrion, although many gaps still remain to be filled in. It is this dissociation which determines the zones of color-change of most of the useful sulfonphthalein indicators. Such information as is available will be found in Table 1. The value of the dissociation constant K_a is expressed in terms of pK_a, which equals $\log \frac{1}{K_a}$.

The names in parentheses are the common laboratory names proposed for the unwieldy ones of the more common compounds.

TABLE 1.—*Apparent dissociation constant of the phenolic hydrion in the sulfonphthaleins*

Substituted phenol	pK_a
2-isopropyl-5-methyl phenol (thymol blue)	8. 90
2, 3-dimethyl phenol (xylenol blue)	8. 9?
*2, 6-dimethyl phenol	8 6
*3-methyl phenol (m-cresol purple)	8. 32

Substituted phenol	pK_a
2-methyl phenol (o-cresol red)	8. 20
phenol (phenol red)	7 90
o-iodophenol	6. 6
*o-bromophenol (brom phenol red)	6. 16
*o-chlorophenol (chlor phenol red)	5 98
2, 6-dibromophenol (brom phenol blue)	4. 05
*2-bromo-6-chlorophenol (brom-chlor phenol blue)	3 98
*2, 6-dichlorophenol	4 0?
2, 6-dinitrophenol	3 3?
6-bromothymol (brom thymol blue)	7 10
6-bromo-2, 3-xylenol	7 1?
6-bromo-2-methyl phenol (brom cresol purple)	6. 30
*2, 6-dichloro-3-methyl phenol (chlor cresol green)	4. 8
*2, 6-dibromo-3-methyl phenol (brom cresol green)	4. 67

The compounds marked with an asterisk were synthesized by the author, and, with the exception of the 2, 6-dichlorophenol derivative (tetrachloro-phenolsulfonphthalein) were of sufficient purity to give well-defined dissociation constants. The sample of di-iodo-phenolsulfonphthalein (o-iodophenol derivative) was obtained from the National Aniline & Chemical Co The data for the other compounds were obtained from Brode (1924), Clark, Cohen, and Elvove (1922), and A Cohen (1922, 1923).

A mere inspection of this table discloses the following important facts: Alkyl groups depress the dissociation of the phenolic hydrogen and halogens increase it. Considering the effects of alkyl substitution more in detail, it will be noted that meta-substitution has a greater effect than ortho-substitution, that di-substitution has a greater effect than mono-substitution, and that a combination of ortho plus meta-substitution is more effective than di-ortho substitution. The data are not extensive enough to disclose the effect of the heavier isopropyl group as compared with the methyl.

Mono-halogenation in the ortho position increases the ionization of the phenolic hydrogen in the order, iodo < bromo < chloro. Attempts to prepare meta-halogen sulfonphthaleins have been unfruitful, but should the synthesis be accomplished, it will probably be found that the effect on ionization is rather less than that of ortho-halogenation. In terms of pK_a differences, di-halogenation has twice the effect of mono-halogenation This mode of designating the effects on ionizations is very useful, but the reader should keep in mind that the pK_a differences are direct functions of differences between the *energies* of ionizations and not between the *magnitudes* of the dissociation constants.

Rather noteworthy is an apparent reversal in the order of effect upon ionization of the phenolic hydrion by chlorine and bromine in di-ortho halogenation on the one hand and tetra-ortho halogenation on the other. In phenolsulfonphthalein, dichlorination produces a

greater effect than dibromination; and while this effect seems to be only diminished (but not reversed) in tetra-chlor- and tetrabromphenolsulfonphthaleins, we find in the case of m-cresolsulfonphthalein that tetra-bromination has a greater effect than tetra-chlorination.

Analogous effects of approximately the same magnitude were found among the indophenols by Cohen, Gibbs, and Clark (1924a). Their data are reproduced here for purposes of comparison, because the parallelism with the sulfonphthaleins is instructive

Indophenol system	pK_a
carvacrol indophenol	8.8
thymol indophenol	8.7
m-cresol indophenol	8.5
o-cresol indophenol	8 4
phenol indophenol	8 1
m-bromophenol indophenol	7.7
o-bromophenol indophenol	7.2
o-chlorophenol indophenol	7 0

The effects of alkyl substitutions in both the indophenols and the sulfonphthaleins are almost identical. The papers by Cohen, Gibbs, and Clark (1924b) and by Gibbs, Cohen, and Cannan (1925) contain additional information of possible value in predicting the effects of substitution upon ionization of the phenolic hydrion in the sulfonphthaleins and perhaps other systems.

The effect of substitution on the dissociation of the phenolic hydrogen may be visualized somewhat as follows: If a group (or groups) substituted for hydrogen in the phenol nucleus pulls electron pairs toward itself more than the dissociable hydrogen pulls electron pairs toward itself, the escaping tendency of an electron pair should be lowered at least in the immediate neighborhood. This should become evident in an increased ionization of the hydrogen. The converse of this effect should occur if the substituent group tends to repel electron pairs. If alkyl groups be considered repellant and halogen attractive the effects would be those found here.

The dissociation constants of the ionizable groups depend on three factors—(1) the nature of the groups, (2) the influence of other groups, and (3) the effect of electrostatic forces between the ionizing groups. The nature of the groups determines the general order of magnitude of each constant. The other two factors have an influence dependent upon conditions. Each substituent produces an effect upon an ionizable group dependent upon the nature of the substituent and its position. In addition, work is expended in the liberation of the dissociable hydrogen from the electrostatic attraction of the charge or charges on the rest of the molecule.

The complete formulation of all these factors appears to be hopeless at the moment, but some promising attempts in this direction are being made (cf. Simms, 1926).

The above rather incomplete summary regarding the effects of substitution on ionization in the sulfonphthaleins was only partly available at the time we decided to seek the substitute for methyl red, but enough of it was implicit in Clark and Lubs' data to point the way.

Knowing approximately the magnitude and the direction of shift in pK_a value caused by introduction of halogen or methyl groups in the phenol nuclei of the phenolsulfonphthalein molecule, it was deduced that a tetra-halogenated m-cresolsulfonphthalein should have a pK_a value close to that of methyl red. Experimental test verified our deduction and resulted in the synthesis of m-cresol purple (pK_a 8 32) and brom cresol green (pK_a 4 67). The latter was proposed as a substitute for methyl red (pK 5.0). Since then chlor cresol green (pK 4 8) has been added. The useful pH ranges of these indicators are given below.

Methyl red	4. 4–6. 0
Chlor cresol green	4 0–5. 6
Brom cresol green	3. 8–5 4

Although these ranges are not identical, they are sufficiently close for practical indicator use; for it is well known that skillful manipulation of conditions permits accurate colorimetric readings beyond the "limits" of the useful ranges. In actual practice we have found that the new indicators can function as adequate substitutes for methyl red.

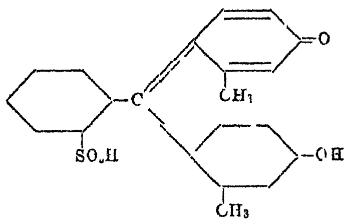
EXPERIMENTAL

m-Cresolsulfonphthalein.—A preliminary report by B. Cohen (1923) was the first announcement of the synthesis of this compound. While the present paper was in preparation there appeared the paper by Orndorff and Purdy [2] (1926) giving a competent elucidation of the chemistry of m-cresolsulfonphthalein.

Orndorff and his associates have shown that the condensation of a phenol with the anhydride of sulfobenzoic acid takes place in two stages, there being first formed an addition product, the intermediate acid, which then reacts with a second molecule of the phenol to give the sulfonphthalein. This process also takes place in the

[2] Orndorff and Purdy, referring to the preliminary report by B. Cohen (1923), state that the latter gave no details as to the method of preparation or the properties of these sulfonphthaleins (m-cresolsulfonphthalein and its tetrabromo derivative), nor were any analyses given. While this statement is correct, these authors appear to have unintentionally overlooked an exchange of letters between Orndorff and Cohen in 1923, in which Cohen responded to a request for information and gave the following essential facts: (1) m-cresol sulfonphthalein was made by condensation of m-cresol with sulfobenzoic acid anhydride at a temperature not exceeding 110° for 10 hours, (2) purification was obtained by dissolving the crude dye in an alkaline medium of about pH 10 to 11, filtering and reprecipitating with acid; (3) slow crystallization from approximately normal HCl or H_2SO_4 yields well-formed crystals with a metallic luster, and (4) analysis of the brominated product had shown it to be the tetra-brom product.

synthesis of m-cresolsulfonphthalein which possesses the following structure:



m-Cresol.—The m-cresol was obtained from Eastman (m-cresol, "practical") and was redistilled before use. The distillate boiled between 200–201° (755 mm.).

o-Sulfobenzoic acid anhydride.—This was made according to the method of White and Acree (1919) from saccharin. It was crystallized out of benzol, and retained a strong odor of benzol. The presence of the benzol was found to be not detrimental.

Condensation of m-cresol with o-sulfobenzoic acid anhydride.—The process must be carried out at a temperature below 110° if m-cresolsulfonphthalein is to be obtained. This has been confirmed by Orndorff and Purdy, who find that higher temperatures favor the formation of dimethylsulfonfluoran, the anhydride of the di-ortho compound. No particular advantage was noted in the employment of condensing agents like zinc chloride so far as improvement in the yield is concerned. The yield is low, between 15 and 20 per cent at the best, and is probably due to a retardative effect exerted by the meta-methyl group.

Crystalline o-sulfobenzoic acid anhydride, 30.8 gm., was added to 36.2 gm. of dry, redistilled m-cresol which had been warmed to 110°. The mixture was stirred and held for six hours in a bath kept at a temperature of 106°. The compound formation was followed by observing the amount of color produced by a test drop in 10 per cent sodium carbonate solution and in dilute acid. The fusion was terminated when color reached a maximum. The mixture was then steam distilled to remove m-cresol. Solid sodium carbonate was then added carefully to the hot solution until the color became deep purple. The solution was allowed to stand overnight to cool and settle out. It was filtered, the precipitate was discarded, and to the filtrate was slowly added concentrated hydrochloric acid until a deep red color developed. This solution was evaporated on the water bath under reduced pressure. Uniform, small green crystals of the sulfonphthalein separated as evaporation progressed. The crystalline product may be washed with cold water to remove adherent acid and salt, and is sufficiently pure (over 95 per cent) for ordinary indicator purposes. The yield up to this point was 12 gm., or about 19 per cent. The residues contain a considerable amount

of coloring matter, but attempts to recover more of the crystalline m-cresolsulfonphthalein from them have not been profitable. Purification is easily effected by dissolving the crystals in hot sodium carbonate solution, filtering, acidifying, and recrystallizing as above by evaporating the solution under reduced pressure.

Analyses.[3]—The air-dried crystals contained from 1 to 3 per cent cent of moisture The material dried to constant weight at 110° gave the following analyses for sulfur. Substance, 0.1500, 0.1500, 0.1500; $BaSO_4$, 0 0891, 0 0903, 0 0911. Calculated for $C_{21}H_{18}O_5S$, S, 8 39 per cent Found, 8 16, 8 27, 8.34 per cent. The compound has no definite melting point. It darkens and contracts at 230° and carbonizes at higher temperatures.

Indicator properties—m-Cresolsulfonphthalein is a brilliant acid-base indicator, and the common name we have suggested for it is *meta-cresol purple* Like the other sulfonphthaleins, it exhibits two distinct sets of color changes corresponding to the dissociations of the sulfonic acid and the phenolic hydrion, respectively. Unlike most sulfonphthaleins, however, its sulfonic acid dissociation (pK_a 1.51) is sufficiently repressed to make it useful as an indicator of acidity in the pH range 1.2 to 2.8, the corresponding color change being from red to yellow. This pH range and virage are identical with those of thymol sulfonphthalein in the Clark and Lubs series.

It has been found, however, that hydrion color standards of thymol blue in the acid range tend to fade with time[4]

Since addition of alkali does not regenerate the faded color of thymol blue, it would seem that the loss of color is due to a decomposition rather than to a mere agglomeration of the dye by the high acidity. Under strictly comparable conditions, hydrion color standards containing meta-cresol purple do not suffer the disadvantage of this slow fading. (It is important to emphasize that the color fading we are now discussing is a slow one, being a matter of days or weeks, and does not affect the ordinary use of thymol blue).[5] We discover, therefore, in meta-cresol purple a brilliant and stable indicator of acidity in the pH region 1.2 to 2.8.

The second color change in meta-cresol purple is from yellow to purple in the pH region 7.4 to 9.0, corresponding to the dissociation (pK_a 8.32) of the phenolic hydrion. In this zone this indicator shares with the other purple indicators the disadvantage of dichromatism, which interferes with the accurate matching of colors. The spectrophotometric data and measurements of the dissociation constants, salt, and protein effects are given in a later section.

---

[3] I am indebted to Chemist Elias Elvove and Assistant Chemist C. G. Remsburg not only for the final analyses presented in this paper but also for numerous preliminary analyses controlling the steps in purification.

[4] This has also been noted by Dr W. A Taylor, of the LaMotte Chemical Co, Baltimore, who now proposes the use of meta-cresol purple as a substitute for thymol blue in the acid range.

[5] Holmes and Snyder (1925a) found this change to be appreciable spectrophotometrically within 24 hours.

Tetrabrom-m-cresol sulfonphthalein (*Brom cresol green*).—The synthesis of this compound was first announced in the preliminary report of B Cohen (1923). It is briefly described by Orndorff and Purdy (1926). A solution of 25 gm. of bromine in 150 c. c. glacial acetic acid was added slowly to a suspension of 15 gm m-cresol sulfonphthalein in 150 c c. glacial acetic acid. The mixture was stirred and not allowed to heat above 30°. At intervals a drop was tested in buffer of pH 7 When the blue color reached a maximum residual bromine was removed by aeration The mixture was then poured into 300 c c water and solid sodium bicarbonate was added until the solution turned definitely green. This was allowed to stand overnight and then filtered. Hydrochloric acid was then added and the solution evaporated. As the acetic acid evaporated off the product separated as a dark, reddish-brown amorphous mass. This material on recrystallization from glacial acetic acid gave a light yellowish product which melted at 217–218° (corr).

Analyses —Several lots of the compound dried to constant weight at 110° yielded the following analyses for sulfur and bromine: Substance, 0.3565, 0.2277, 0.1910, 0 2570; $BaSO_4$, 0 1185, 0.0765, 0.0623, 0.0817; substance, 0.1650, 0.1810, 0.1932, 0.2228; AgBr, 0.1780, 0.1933, 0.2175, 0.2543. Calculated for $C_{21}H_{14}$ Br_4O_5S; S, 4.59 per cent; Br, 45.80 per cent. Found, S, 4 56, 4.62, 4.48, 4 36 per cent; Br, 45.91, 45 45, 45.05, 46.09 per cent.

Indicator properties.—Tetrabrom-m-cresolsulfonphthalein is the compound proposed by B Cohen (1923) as a substitute for methyl red, and the common name proposed for it is *brom cresol green.* It is far more stable in solution than methyl red, and its color changes are distinct. Brom cresol green may be used in the colorimetric determination of hydrion concentration in bacterial cultures to the same extent as the other sulfonphthaleins, although it should be remembered that even these rather stable indicators may be attacked by very active species. Hydrion color standards containing brom cresol green remain unaltered under proper conditions for long periods The color change associated with the ionization of the phenolic hydrion is from yellow to blue (corresponding to the pH zone 3.8 to 5.4), the color at the midpoint, pK_a 4.67, being green. Owing to this moderately high dissociation, brom cresol green gives in ordinary tap water the characteristic blue color of the fully dissociated dibasic salt; and for the same reason this indicator is practically insensitive to CO_2.

The spectrophotometric data and measurements of the dissociation constants, salt, and protein effects are given in a later section.

Tetrachlor-m-cresolsulfonphthalein (*Chlor cresol green*).—Pure m-cresolsulfonphthalein, 8 gm., was suspended in 175 c. c. glacial acetic acid and was chlorinated by bubbling commercial tank chlorine

through the suspension. The subsequent procedure was substantially the same as in the preparation of the tetrabrom derivative The tetrachlor product was finally recrystallized from glacial acetic acid, from which it separated out in small, brown, velvety tufts, melting at 200–201° (corr). On analysis it was found to contain 6 1 per cent S and 27 0 per cent Cl; calculated for $C_{21}H_{11}Cl_4O_5S$, 6 17 per cent S, 27 27 per cent Cl.

Except for a determination of the pK_a by the Salm method, no very detailed examination of the compound was made, hence the data here given should be regarded as only approximate The original purpose in preparing the compound was to determine the effect of tetrachlor substitution as compared with tetrabrom upon the dissociation of the phenolic hydrion

The pK_a of the tetrachlor derivative was found to be 4.8, and we have seen above that in the tetrabrom compound it is 4 67 The color change in both compounds is the same, from yellow to blue, but the pH ranges are slightly different, corresponding to the differences in pK_a values The pH range of chlor cresol green is 4 0 to 5.6, a slightly closer approach to the range of methyl red than is given by brom cresol green

Dibrom-phenolsulfonphthalein —In the colorimetric determination of hydrion concentration, a matter of minor importance but yet of great convenience is the color of the indicator itself, a factor which is determined by the nature of the solution as well as by the physiology and psychology of color perception. We may encounter amongst apparently normal persons a greater ease in distinguishing color gradations in the reds than in the blues, and vice versa. Another factor of still greater importance in this connection is the dichromatism especially of the purple indicators, which introduces real difficulties in the accurate matching of colors

The elimination of such troublesome indicators is greatly to be desired if adequate substitutes can be found. In the Clark and Lubs series brom cresol purple and brom phenol blue are the chief offenders, and we have succeeded in producing an excellent substitute for the former in *brom phenol red* (dibrom-phenolsulfonphthalein) which is a clear red in solutions where brom cresol purple is either blue or red, according as the liquid layer is thin or thick

Brom cresol purple has a pK_a value of 6 3, and from the fact that tetra-brom phenolsulfonphthalein has a pK_a of 4 05 while that of phenolsulfonphthalein is 7 90, it is to be expected that the dibrom compound should have a pK_a about midway between these two and therefore approximately that of brom cresol purple.

In addition it was expected that the color of the new compound in alkaline solution would show more of the red of phenol red and less

of the blue of brom phenol blue This was deduced from the fact that halogenation in the sulfonphthaleins tends to introduce a blue component in the color of the unhalogenated compound. Thus, tetrabrom-phenolsulfonphthalein is blue while phenolsulfonphthalein is red, dibrom-o-cresolsulfonphthalein is purple while o-cresolsulfonphthalein is red, and dibrom-thymolsulfonphthalein is blue while thymolsulfonphthalein is purplish blue This deduction was confirmed, but the elimination of the blue component occurred to a greater degree than was expected, for the alkaline color of dibrom-phenolsulfonphthalein exhibits only a slight suggestion of blue.

Sohon (1898) describes the synthesis and properties and gives analyses of a compound alleged to be dibrom-phenolsulfonphthalein We find that although his analyses correspond to such a compound, the properties described are those of tetra-brom-phenolsulfonphthalein and the method of synthesis yields the tetra-brom product and nothing else. We are unable to account for the apparent discrepancy

When phenolsulfonphthalein is brominated in glacial acetic acid (the method followed by Sohon) there results tetrabrom-phenolsulfonphthalein, and when the bromination is incomplete the result is a mixture of the unbrominated and tetra-brominated compounds. Analogous effects are produced by chlorination.

We have prepared the dibrom compound and found it to possess properties distinct from the tetra-brom. Moreover, we have confirmed its identity by brominating it and producing the tetra-brom derivative The change in pK value of the successively brominated derivatives furnishes independent confirmatory evidence

Synthesis.—The o-bromophenol employed came from two sources—some was prepared in this laboratory and some was purchased from Eastman Kodak Co. Thirty-four grams of o-bromophenol was heated to 140° and 18.1 grams o-sulfobenzoic acid anhydride was added and stirred in. The mixture was kept in an oil bath at 140° for about 10 hours, or until a test drop showed maximum color production. Water was then added and the mixture steam distilled to remove residual bromophenol. Solid sodium bicarbonate was then cautiously added until the solution was a deep bluish red. After standing overnight the solution was filtered. The filtrate was poured slowly into 20 per cent hydrochloric acid and the compound separated out in bright red granular masses. On standing the material assumed a crystalline form with a greenish lustre.

The product is surprisingly soluble in water. It was therefore thoroughly washed with dilute hydrochloric acid, dried over stick sodium hydroxide, and heated in the oven to remove adherent hydrochloric acid. The mother liquor contained a considerable proportion of the compound, which was recovered by evaporation and extraction

with n-butyl alcohol The purified dibrom-phenolsulfonphthalein, recrystallized from glacial acetic acid, melted at 230° (corr)

Analyses—Substance, 0 2538, 0 1587, $BaSO_4$, 0 1159, 0.0713; substance, 0 1500, 0 1500, AgBr, 0 1100, 0 1104 Calculated for $C_{19}H_{12}O_5SBr_2$. 6.26 per cent S and 31 21 per cent Br. Found, 6.27, 6 17 per cent S, and 31 21, 31 32 per cent Br.

Indicator properties—Dibrom-phenolsulfonphthalein, *brom phenol red* for short, has the brilliant indicator properties characteristic of the sulfonphthaleins It is soluble in water to the extent of at least 0 2 per cent, yielding a golden yellow solution In strongly acid solution it gives an orange-red color, in intermediate zones the color is yellow, and in alkaline solution it is deep red Its useful range for the colorimetric determination of hydrions is between pH 5.2 and 6 8, corresponding to a pK_a of 6 16 Brom phenol red is an almost perfect substitute for brom cresol purple and is free from the disturbing property of dichromatism

Purified brom phenol red appears to be perfectly stable, but we have noted in the case of some of our crude preparations a certain amount of fading This tendency was eliminated by purification of the material In this connection it is interesting to note that we found a specimen, labeled brom phenol red and sent to us for examination, to have the properties of phenol red and not of brom phenol red. This has also been encountered by Rous (1925). These, may however, be merely cases of accidental mislabeling.

In this connection it is possible that the fading of acid solutions of thymol blue, which we have previously discussed, may be due to impurities in that compound

Dichlor-phenolsulfonphthalein.—This compound was made in order to determine the effect of dichlor substitution as against dibrom substitution on the ionization of the phenolic hydrion in the corresponding sulfonphthaleins.

Synthesis—o-Chlorophenol was the starting material. Both the Eastman product and material prepared in this laboratory were used. Thirty-two grams of dry o-chlorophenol was heated to 130° and 23 grams crystalline o-sulfobenzoic acid anhydride was stirred in. The mixture was heated for six hours at 130°, or until a test drop showed maximum color formation. Water was then added and the mixture steam-distilled to remove residual chlorophenol. Sodium bicarbonate was then carefully added until the color became a deep bluish red, and the solution was allowed to stand overnight before filtering Concentrated hydrochloric acid was added to the filtrate until a precipitate formed. This was filtered off and washed with dilute hydrochloric acid. Water can not be used for washing because of the solubility of the compound. The mother liquor was evaporated and a second crop of crystals was obtained. The adherent moisture

and hydrochloric acid may be driven off with heat. The crystals are very small and are of dark green color with a reddish tinge, and when ground the material is dark red. When recrystallized from glacial acetic acid it yields a product melting at 261–262° (corr.).

Analyses.—Substance, 0.1500, 0.1500; $BaSO_4$, 0.0810, 0 0815; substance, 0 1500, 0.1500; AgCl, 0 1017, 0 1020. Calculated for $C_{19}H_{12}O_5SCl_2$, 7.58 per cent S and 16.76 per cent Cl. Found, 7.42, 7 46 per cent S, and 16 77, 16 82 per cent Cl

Indicator properties—Dichlor-phenolsulfonphthalein, *chlor phenol red* for short, is very similar to brom phenol red in solubility and in indicator properties Its alkaline color is a deep red with even less of a bluish cast than is seen in brom phenol red. The alkaline color of a commercial specimen of the corresponding di-iodo compound was found to be decidedly purplish. We see, therefore, that increasing weight of the halogen substituent tends to introduce an increasing amount of blue in the colors of the corresponding compounds.

The useful range of chlor phenol red for the colorimetric determination of hydrions is between 4.8 and 6.4, corresponding to a pK_a of 5 98. Chlor phenol red overlaps the range of brom cresol green on the one hand and of brom thymol blue on the other. Consequently, both methyl red and brom cresol purple, two objectionable compounds as above indicated, may be eliminated from the Clark and Lubs series of indicators without leaving a gap.

Dibrom-dichlor-phenolsulfonphthalein (Brom-chlor phenol blue).—By brominating dichlor-phenolsulfonphthalein or chlorinating the dibrom compound it is possible to obtain a dibrom-dichlor derivative. It was of interest to obtain this compound and compare its properties with those of the tetrabrom and tetrachlor derivatives.

Synthesis.—Dichlor-phenolsulfonphthalein was brominated in glacial acetic acid at room temperature The bromination was terminated when a test drop showed maximum development of purple-blue color in alkaline solution Residual bromine and hydrobromic acid were removed by aeration. Water was added and then solid sodium bicarbonate until the yellow color changed to a deep wine red. The solution was filtered after settling overnight, and to the filtrate was added concentrated hydrochloric acid. The compound separated out as a dark brown precipitate. The mother liquor was evaporated under reduced pressure, and a second crop was obtained. The material was recrystallized from benzol and glacial acetic acid, yielding a flesh-pink powder melting at 250–251° (corr.).

Analyses.—Substance, 0.2000, 0.2000; $BaSO_4$, 0 0778, 0.0752; substance, 0.2000; AgBr 0 1271; AgCl, 0 1013. Calculated for $C_{19}H_{10}O_5SBr_2Cl_2$, 5.52 per cent S, 27.51 per cent Br, 12.21 per cent Cl. Found, 5.31 and 5.16 per cent S, 27.05 per cent Br, 12.53 per cent Cl.

Indicator properties.—Dibrom-dichlor-phenolsulfonphthalein, *bromchlor phenol blue* for short, is very similar to brom phenol blue in indicator properties It imparts a yellow color to mineral acid solutions of around 0 01N and a purplish blue to more alkaline solutions, in which is exhibited the troublesome dichromatism shared by brom phenol blue. Its useful range for the colorimetric determination of hydrions is between pH 3 0 and 4.6, corresponding to a pK_a of 3.98 for the ionization of the phenolic hydrion

Comparing the pK_a values of the tetra-brom compound (4 05) and the dibrom-dichlor compound (3.98), we note that the effect is only a relatively slight increase in ionization of the phenolic hydrion when two bromine atoms are replaced by two chlorines From this it may be inferred that the pK_a value of the tetra-chlor derivative will be shifted still further and to the same slight degree A crude specimen of tetrachlor-phenolsulfonphthalein was prepared (but not purified or analyzed) and its pK_a value, as determined by the Salm (1906) method, was found to be about 4 0

Xylenol-sulfonphthaleins —Xylenol blue, made from 2, 3-dimethyl phenol has been synthesized by A. Cohen (1922). Its pK_a value is approximately 8.9, like that of thymol sulfonphthalein. It is to be expected that the compound made with 2, 5-dimethyl phenol will have approximately the same dissociation constant for the phenolic hydrion. On the other hand, the compound made with 2, 6-dimethyl phenol should show a lower pK_a value because of a lesser suppression of the phenolic ionization by o-methyl substitution as compared with m-methyl substitution. By the same reasoning, the compound made with 3, 5-dimethyl phenol (symmetrical m-xylenol) should show a much higher suppression of ionization of the phenolic hydrion (pK_a about 9.5).

We did not have available any 2, 5-dimethyl phenol for confirming the one aspect of our predictions, but 2, 6-dimethyl phenol[6] and 3, 5-dimethyl phenol were available We found that condensation of 2, 6-dimethyl phenol with o-sulfobenzoic acid anhydride yielded a sulfonphthalein similar in indicator properties to xylenol blue and having a pK_a of 8.6 The compound (2, 6-xylenol sulfonphthalein) crystallized in beautiful, reddish bronze masses melting at 253–254° (corr). No analyses were made. The behavior of this compound confirmed our prediction.

However, numerous attempts to prepare the symmetrical xylenol derivative were unsuccessful Pure 3, 5-dimethyl phenol was prepared by the Knoevenagel reaction from ethyl aceto-acetate according to the method described by Gattermann (1923). The *sym*-xylenol was condensed in a variety of ways with the sulfobenzoic acid anhy-

[6] We are grateful to Dr L H Marks, of the National Aniline & Chemical Co., who supplied us with a pure specimen of this compound

dride, but no sulfonphthalein was obtained. We have already seen that the yield on condensing m-cresol with the anhydride is very low, and it would seem that the presence of two meta-methyl groups completely hinders the condensation to a sulfonphthalein by the ordinary procedure Some other method of synthesis will have to be devised to produce this compound, and when it is accomplished we believe our prediction as to its pK_1 value will be verified.

SPECTROPHOTOMETRIC MEASUREMENTS

Measurements in the visible and ultraviolet ranges of the spectrum made by Orndorff, Gibbs, Scott, and Jackson (1921) have shown that the sulfonphthaleins in neutral aqueous solution have two absorption bands The addition of either acid or alkali results in the disappearance of one of the bands and the appearance of two new absorption bands, one on each side of the position of the band that disappears The other band of the neutral solutions seems to be modified by the addition of acid, but with the addition of alkali it also disappears and a new band with lower frequency appears In the case of dilute alkaline solutions the new type of absorption is not stable but reverts more or less rapidly to the two absorption bands found in the corresponding neutral solution These changes and reversions indicate that in the neutral aqueous solutions the carbinol and hydrate forms of the sulfonphthalein are present and that on the addition of either acid or alkali a salt having a quinoid structure is formed.

The absorption curves of aqueous solutions of most of the new sulfonphthaleins were determined in the visible region with a Keuffel & Esser, Model E, direct reading color analyzer, employing tubes 10 cm. long. The wave-length scale was graduated to 5 millimicron intervals and the photometer in unit steps from zero to 100.

A stock aqueous solution was prepared containing 0.04 per cent of the indicator plus one equivalent of NaOH. The solution was diluted 1:9 with water, and this dilution was further diluted 1:19 with acid, alkali, or the required buffer (as indicated below) to produce complete color transformation and to permit viewing through a 10 cm. thickness of solution The final concentration of indicator was 2 0 mg. per litre, except as noted in certain cases The measurements were carried out at 30°.

The peaks of the absorption bands were found to be at the following wave lengths (1 $m\mu = 10^{-6}mm = 10$ Angstrom).

	$m\mu$
Meta-cresol purple (acid range)	533
Meta-cresol purple (alkaline range)	580
Brom cresol green	617
Chlor cresol green	612
Brom phenol red	574
Chlor phenol red	573
Brom-chlor phenol blue	596

We found the absorption peak of brom phenol blue to be at 593mμ, which is in fair agreement with the value (592mμ) found by Brode (1924). For brom cresol green, Holmes and Snyder (1925b) report the peak at approximately 614mμ, and we find it near 617mμ.

The absorption curves in the visible spectrum are shown in the accompanying charts (fig 1) and the experimental data in Table 2. The absorptions are given in terms of $-\log_{10}$ transmittancy ($-\log_{10}T$), which is identical with the product of the thickness, concentration, and the specific transmissive index, k. (cf. Gibson et al., 1922)

m-Cresol purple—The full acid color was developed in conc HCl, the neutral color in Clark and Lubs' phthalate buffer of pH 4 6, and the alkaline color in N/5 NaOH.

Brom cresol green, chlor cresol green, brom phenol red—The full alkaline colors were developed in Clark and Lubs' borate buffer of pH 10 The concentration of brom phenol red was 1 6 mg. per liter.

Chlor phenol red—The full alkaline color was developed in N/5 NaOH

Brom-chlor phenol blue—The full alkaline color was developed in Clark and Lubs' borate buffer of pH 9 2

FIG 1

SPECTROPHOTOMETRIC DETERMINATION OF THE APPARENT DISSOCIATION CONSTANTS

The degree of transformation of an indicator within the range of its utility depends upon the hydrion concentration of its solution; and Brode (1924) and Holmes (1924, 1925) have shown how it may be measured with relative accuracy with the aid of the spectrophotometer All that is necessary is to determine under comparable conditions of concentration and temperature the ratio of color absorption within the useful pH range of any wave length in the absorption band (preferably at the peak) to that of the same wave length in the completely transformed compound This ratio gives the percentage dissociation of the indicator at the particular pH of the solution measured. The apparent dissociation constant, pK_a, of the indicator can then be calculated by the familiar equation:

$$pK_a = pH - \log \frac{\alpha}{1-\alpha}$$

where α is the degree of dissociation

This procedure yields consistent results, and in the case of brom cresol green we have been able to confirm the value obtained by Holmes and Snyder (1925b).

Suitable dilutions of each indicator were made in acid, alkali, or Clark and Lubs' buffers, as the case required, to produce complete color transformation, and these were compared with the same quantity of indicator in buffers of known pH.

All measurements were carried out at 30°.

m-Cresol purple, acid range.—The acid form of the indicator is red, with an absorption band in the yellow, the peak lying at 533 mμ. The accurate determination of the dissociation constant depends on obtaining complete dissociation of the indicator, and we found concentrated HCl necessary to produce complete acid transformation of m-cresol purple, just as Holmes and Snyder did for the acid range of thymol blue. The results are summarized in Table 3.

TABLE 3—*m-Cresol purple (acid range). Absorption maximum at 533mμ*

Buffer (pH)	pH electrometric	Conc. mg. per liter	T	−log T	α	$\log \frac{\alpha}{1-\alpha}$	pK_a

Average							1 51

* Corrected to concentration of 1.6 mg per liter.

It will be seen from the table that the pK_a values obtained near the middle of the dissociation curve agree fairly closely, the average value being 1.51.

m-Cresol purple, alkaline range—As the alkalinity of the indicator solution is increased through the pH range 7.0 to 11.0 the indicator becomes progressively and completely transformed to its alkaline form, which is purple in color, with an absorption band in the yellow, the peak lying at 580mμ. The apparent dissociation constant was determined spectrophotometrically, the fully transformed alkaline form of the indicator being produced in N/5 NaOH The data are summarized in Table 4. The average pK_a value found is 8.32

Brom cresol green.—The peak of the absorption band of the alkaline form of this indicator lies at 617mμ Clark and Lubs' borate buffer pH 9.6 was used to produce the alkaline transformation The average pK_a value found is 4 67, which agrees with that found by Holmes and Snyder (1925b). Our experimental data are summarized in Table 5. In our preliminary note, B Cohen (1923) this value was stated to be 5 0, as determined by the Salm method. We have found on subsequent repurification of the indicator that the apparent dissociation constant went down and remained constant at 4 67, although the bromine and sulfur analyses remained substantially unchanged (cf. Holmes and Snyder (1925b)).

TABLE 5.—*Brom cresol green Absorption maximum at 617mμ*

[1] Corrected to concentration of 1.6 mg per liter

Brom phenol red.—The absorption peak of the alkaline form of this indicator lies near 574mμ. Clark and Lubs' borate buffer pH 10.0 was used to produce the full alkaline color. The average pK_a value found is 6.16, and the data are summarized in Table 6. We have noted in some specimens of this indicator a peculiarity not observed in the other sulfonphthaleins examined. Alkaline solutions of these specimens showed a progressive decrease in absorption with time. In other repurified specimens there was no such change, and we are therefore inclined to ascribe this peculiar behavior to impurities.

"SALT ERRORS" OF THE NEW INDICATORS

In the absence of a satisfactory theory that will permit calculation of the salt errors of indicators, the only reliable procedure is to determine these errors by direct hydrogen electrode measurements This has been done for those of the new sulfonphthaleins that are regarded as useful supplements to the Clark and Lubs series

Sodium chloride was added to various Clark and Lubs buffers so as to bring the solutions to 1 molar concentration (the electrolyte in the 0 02 M buffer being calculated in terms of NaCl) For measuring the salt error of m-cresol purple, acid range, the "1 M" buffer contained 53.110 gm NaCl, 250 c c. M/5 KCl and 207 5 c c. M/5 HCl per liter; for the alkaline range the "molar" buffer contained 52.268 gm NaCl, 250 c c. M/5 H_3BO_3, M/5 KCl and 29 5 c. c M/5 NaOH For brom phenol red and chlor phenol red the "molar" buffer contained 55 204 gm. NaCl, 250 c. c. M/5 KH_2PO_4 and 89 00 c c. M/5 NaOH per liter For brom cresol green and brom-chlor phenol blue the "molar" buffer contained 55 32 gm NaCl, 250 c. c. M/5 KH-phthalate, and 18.5 c c M/5 NaOH per liter.

These "molar" solutions were then diluted to 0.5 M, 0 2 M, and 0.005 M.

Hydrogen ion measurements were taken of the various solutions, both electrometrically and colorimetrically, the basis of the colorimetric comparisons being the standard Clark and Lubs buffers. The measurements were all made at 30°. The hydrogen electrode determinations were referred to M/20 KH-phthalate (pH 3.97) as a standard. The indicator solutions were 0.04 per cent concentrations of the mono-sodium salts in water These were prepared in the manner outlined by Clark (Determination of Hydrogen Ions, 2d ed., p. 80–81), the equivalents of N/20 NaOH per 100 mg. indicator being as follows:

TABLE 9.—*Quantities of NaOH to produce mono-sodium salts of indicators*

Indicator	Mol weight	N/20 NaOH per 100 mg.
		c. c.
m-Cresol purple	382.2	5.3
Brom cresol green	698.0	2.9
Brom phenol red	512.1	3.9
Chlor phenol red	423.2	4.7
Brom-chlor phenol blue	581.0	3.4

The differences between the electrometric and colorimetric pH values were determined and are summarized in Table 10 as corrections.

TABLE 10.—*Salt effect on the new sulfonphthaleins*

[The values given below are corrections to be added to the colorimetric pH determinations to bring the values to the electrometric pH of the corresponding Clark and Lubs' buffers]

Molar conc. salt	m-Cresol purple		Brom cresol green	Brom phenol red	Chlor phenol red	Brom-chlor phenol blue
	Acid range	Alkaline range				
1.0	−0.14	−0.29	−0.32	−0.26	−0.26	−0.33
0.5	−.09	−.22	−.25	−.22	−.20	−.28
0.2	−.02	−.16	−.16	−.12	−.10	−.16
0.005	+.11	+.09	+.09	+.25	+.23	+.14

Similar results were obtained in another series of experiments with brom cresol green. In this case a normal sodium citrate solution was used, containing 250 c. c. molar citric acid and 500 c. c. normal NaOH. The colorimetric comparisons were made against Clark and Lubs' buffers. The pH corrections found for the salt effect are given below.

1.0 normal	−0.20
0.5 normal	−.19
0.2 normal	−.09
0.1 normal	−.03

The salt effect at high salt concentrations appears to be least for m-cresol purple in acid ranges and greatest for brom-chlor phenol blue. As the salt concentration decreases toward 0.1 molar the effect becomes practically negligible. With still greater dilutions the sign of the salt "error" changes and becomes quite appreciable at 0.005 molar salt (cf. Kolthoff, 1925, and Lepper and Martin, 1926).

"PROTEIN" EFFECT

Protein material in solutions containing indicators exerts specific effects on the colors, effects dependent on the nature not only of the indicator but also of the protein and apparently on its previous

treatment. The only safe procedure when attempting the colorimetric determination of pH in protein solutions is to calibrate the readings of the particular indicator in the specific protein solution with the hydrogen electrode.

The following data are presented merely to show the magnitude of the effect produced by a certain peptone upon the sulfonphthalein indicators. Incidentally, the sulfonphthaleins in the Clark and Lubs series were also included so as to have a comparable set of data. All observations were made at least in duplicate and were consistent. Colorimetric readings were made to the nearest 0.05 pH against Clark and Lubs' buffers. Quadruplicate hydrogen electrode measurements had to agree within 0.5 mv before being accepted. The determinations were made at 30°.

The peptone solution was a 5 per cent concentration of Witte's peptone, which was boiled and filtered. To aliquots of this stock peptone solution were added small quantities of conc. HCl or NaOH to bring the pH within the range of the particular indicator studied. In most of the cases a more or less distinct opalescent haze appeared after the addition of acid or alkali, but the colorimetric and electrometric readings remained unchanged after filtration of such solutions.

The same experiment was repeated two months later. The same lot of peptone was used and apparently the same technic. The results disclosed certain divergencies which we are unable to explain. There was substantial agreement in the results for the indicators of the acid regions down to brom cresol green, but below that the two series tend to diverge. The data are summarized in Table 11.

TABLE 11.—"*Protein effect*" *on sulfonphthalein indicators*

[The values listed are the corrections to be added to colorimetric pH readings to bring them to the electrometric]

Indicator	In 5 per cent Witte peptone		Clark and Lubs[1]
	Series 1	Series 2	
m-Cresol purple (acid)	−0.20	−0.20	
Thymol blue (acid)	−.19	−.20	
Brom phenol blue	−.28	−.43	+0.05
Brom-chlor phenol blue	−.28	−.43	
Brom cresol green	−.10	−.13	
Chlor phenol red	+.09	−.07	
Brom phenol red	+.11	−.10	
Brom cresol purple	+.11	−.10	+.01
Brom thymol blue	+.31	+.07	+.10
Phenol red	+.24	−.01	+.04
Cresol red	+.02	−.03	+.03
m-Cresol purple (alk.)	+.03	−.02	
Thymol blue (alk.)	+.09	−.03	+.04

[1] In a 1 per cent peptone-beef infusion broth.

For purposes of comparison there is included in Table 11, under the column headed Clark and Lubs, the corrections found by these authors (1917) for a 1 per cent peptone-beef infusion broth. While a strict comparison could scarcely be considered valid, it nevertheless is useful in a rough survey of the ground. Our results show the general magnitude of the effect produced on the colorimetric reading by the presence of 5 per cent peptone. Their main value lies in again emphasizing the dictum that "protein effects" have to be determined experimentally for the material under examination and that calibration is not a simple matter.

SUMMARY

The following new sulfonphthaleins have been synthesized: m-cresolsulfonphthalein, tetra-brom-m-cresolsulfonphthalein, tetra-chlor-m-cresolsulfonphthalein, dibrom-phenolsulfonphthalein, dichlor-phenolsulfonphthalein, dibrom-dichlor-phenolsulfonphthalein, and 2, 6-xylenol sulfonphthalein. The effects of substitution on dissociations in the sulfonphthaleins are discussed, and certain predictions based on an empirical formulation of the effects have been verified.

All but the last mentioned of these compounds are recommended as useful supplements to the Clark and Lubs series of acid-base indicators, or as substitutes for certain unsatisfactory members in that series. The new compounds have been studied as to their indicator properties, spectrophotometric behavior in the visible region, apparent dissociation constants, salt, and protein effects. The essential characteristics are summarized in Table 12.

TABLE 12.—*Summary of characteristics of the new sulfonphthalein indicators*

Sulfonphthalein	Common name	Absorption max [1]	pK_a	Useful pH range	Color change
m-Cresol	m-Cresol purple	[2] 533	1.51	1.2-2.8	Red-yellow.
		[3] 580	8.32	7.4-9.0	Yellow-purple.
Tetra-brom m-cresol	Brom cresol green	617	4.67	3.8-5.4	Yellow-blue
Tetra-chlor m-cresol	Chlor cresol green	612	4.8	4.0-5.6	Do
Dibrom phenol	Brom phenol red	574	6.16	5.2-6.8	Yellow-red.
Dichlor phenol	Chlor phenol red	573	5.98	4.8-6.4	Do
Dibrom dichlor phenol	Brom-chlor phenol blue	596	3.98	3.0-4.6	Yellow-blue.

[1] The absorption maxima are for the (alkaline) disodium salts, except in the case of m-cresol purple, acid range, where the value given refers to the absorption of the free acid.

SMALLPOX IN MINNESOTA—1913-1925

In the Public Health Reports of December 3, 1926, page 2789, appears the statement that 1,298 cases of smallpox with 63 deaths had occurred in Minneapolis, Minn. Dr. A. J. Chesley, State health officer of Minnesota, advises that the number of deaths was 363, not 63, which gives a case fatality in this series of cases of more than 25 per cent

Doctor Chesley sends the following statement of vaccination histories of smallpox cases which have occurred in Minnesota:

MINNESOTA, SMALLPOX

1925—Total cases, 973, total deaths, 198

Class A.—Successfully vaccinated within seven years before attack, 15 cases, or 1 54 per cent; 1 death, or 0.51 per cent.

Class B—Successfully vaccinated over seven years before attack, 191 cases, or 19.63 per cent; 41 deaths, or 20.71 per cent.

Classes C and D.—Class C, never successfully vaccinated, and Class D, unable to give definite history of vaccination and no scar found, 767 cases, or 78.83 per cent; 156 deaths, or 78 78 per cent.

1913-1925—Total cases, 39,250, total deaths, 613

Class A—661 cases, or 1 68 per cent of all, 1 death, or 0.16 per cent of all deaths from smallpox.

Class B—1,976 cases, or 5 03 per cent of all: 89 deaths, or 14 52 per cent of all deaths from smallpox

Classes C and D.—36,613 cases, or 93 28 per cent of all, 523 deaths, or 85 32 per cent of all deaths from smallpox.

Vaccination history of 505 fatal cases in Minnesota

	1924	1925	Total
Class A	0	1	1
Class B	47	41	88
Class C	243	151	394
Class D	17	5	22
Total	307	198	505

PUBLIC HEALTH ENGINEERING ABSTRACTS

Lead Poisoning From Food.—Anon. *The Lancet,* No 5375, September 4, 1926, p 507.

"The story is told in the *Presse Médical* of an outbreak of lead poisoning which commenced at Vidin, in Bulgaria, during April, 1923, and terminated only when its origin was detected five months later. By that time there had been 314 cases, occurring in 153 families, with three deaths, while several other deaths occurred among those poisoned as a result of other disorders considered to have been brought on or at least accentuated by the lead absorbed; notably one case of cancer of the rectum in a woman aged 28 is attributed to this cause. The number of cases ranks the epidemics with others, such as have followed upon accidentally mixing of white lead with flour, from drinking plumbo-solvent water by the royal household at Versailles in the eighteenth century, and from Loch Katrine, in Glasgow, at the end of the nineteenth century, and the 350 cases at Saint-Georges-sur-Eure in 1865. The signs and symptoms appear to have been quite typical; the blue line was present in 99 per cent of cases, lead colic was frequent and affections of the nervous system, with 3 cases (1 fatal) of encephalopathy. Nephritis and wrist drop, symptoms of chronic lead poisoning, were not observed. The source of the poisoning was found to be adulterated red pepper. This pepper, prepared from capsicum fruit, is much used in Hungary and Bulgaria, and it is often adulterated with such things as maize or vetch flour, sawdust, iron filings, or brick dust, but on this occasion analysis revealed the presence of 20.5 per cent of red lead and 4.1 per cent of sand, while very small amounts of true pepper were found.

This fraudulent "red pepper" was placed on the market by only one firm, and inhabitants who bought their red pepper elsewhere or made it themselves escaped Most of the cases followed the ingestion of a number of small doses, a teaspoonful of pepper serving two to four persons for several days; but one case followed a single dose of two teaspoonfuls of "pepper," containing about 6 grains of red lead, taken at one meal; the case recovered "

Outbreak of Paratyphoid Fever Due to Infected Ice Cream.—J. P. Kinloch. (*The Medical Officer.* 1925, v 34, pp. 191–192.) Abstract by W. G. Savage in *Bulletin of Hygiene*, vol. 1, No. 2, February, 1926, p. 101.

"An outbreak of 23 cases, all but 2 in Aberdeen, of paratyphoid fever in August, 1925. The symptoms were all of this disease and none were of food-poisoning type. For example, in all the cases the onset was characteristically insidious; and while vomiting was not uncommon, when present it was slight. In general, constipation and not diarrhea was the rule. Rose spots were present in most cases. Although a number of the cases were severe, there were no deaths. The incubation period was about 15 days.

"Careful epidemiological inquiry showed that the one article of food consumed in common was ice cream, obtained from one particular shop The milk used to make the ice cream was naturally the object of suspicion, but milk from the same source used elsewhere produced no disease. About 6 gallons of milk were daily converted into ice cream on the incriminated premises The staff on these premises was investigated, but no evidence of previous illness of any member was forthcoming and the bacteriological examinations were negative. *It was not possible to ascertain how the ice cream became* infected, but direct or indirect contamination by a paratyphoid B 'carrier' was considered as the most likely source. Investigations could not be undertaken until three weeks after the ice cream became infective.

"The outbreak was definitely proved to be paratyphoid fever by the isolation of *B. paratyphosus* B from the feces of eight sufferers and from the urine of two cases, and by the demonstration of specific agglutinins in the blood of all the cases.

"A point of interest is that the ice cream on the day it was infective was distributed to between 120 to 360 people, while only 23 developed the disease. Probably only part of it was infected and the freezing prevented distribution of the bacilli throughout the whole mass."

Clean and Safe Milk Campaign to Stimulate Use.—S. J. Crumbine, general executive, American Child Health Association, New York City. *The Nation's Health*, vol. 8, No. 8, August, 1926, pp. 530–532. (Abstract by H. N. Old.)

Some very significant facts and figures on milk-borne epidemics of communicable diseases are tabulated and commented upon, as obtained from questionnaires covering 42 States, the District of Columbia, 3 Territories, and 3 Canadian Provinces.

During 1924 and 1925, 43 and 44 such epidemics are reported, respectively, with a total for the two years of 3,286 cases and 130 deaths, typhoid epidemics constituting 72 per cent of the total reported.

The danger from tuberculous cows is dwelt upon at length and the conclusion reached by Park and Krumwiede is stated—that 27 per cent of tubercular children under 5 and 25 per cent of those between 5 and 16 years of age are found to have infection of the bovine type.

Up to the present time 12 States have been surveyed, 179 towns covered, 3,945 supplies and 4,928 samples examined for visible dirt, bacteriological contamination, and detection of adulteration, Standard Methods being followed. Summarizing the survey results, it is stated that 77 per cent of the samples were classed as dirty, 58 per cent showing bacterial count over 100,000, with 43 per cent positive for colon bacillus, and about 14 per cent adulteration.

The objectives of the campaign are, first, stimulation of the production and distribution of an abundant, clean, and safe milk supply; second, to center the responsibility for such production and distribution on dairymen, milk dealers, and State and local dairy and health officials; and third, to promote increased consumption of milk after reasonable assurance of its safety.

The by-products of the survey thus far are said to be most encouraging, resulting in the promotion of a clean-up among the dairymen and dealers, provision of local supervision using laboratory examinations in many instances, and commitments made toward a general tightening of milk-control regulations.

While the survey shows the daily per capita milk consumption to be only 0.6 to 0.8 pint, the conclusion is reached that, in many communities, increased consumption should not be urged until the safety of the supply is assured

The organizations cooperating actively in this work are the American Child Health Association, the Association of Dairy, Food, and Drug Officials, and the Conference of State and Provincial Health Authorities.

Bacterial Flora of the Market Oyster.—Calista Eliot. *The American Journal of Hygiene*, vol. 6, No. 6, November, 1926, p. 755.

(1) Shucked oysters and shell oysters kept at the laboratory temperatures show a sudden and maximum rise in total count from the second to the fourth day of storage; (2) the *Bacillus coli* score of oysters stored in a cool basement increased from 4 to 500,000 in 14

days; as signs of spoilage appeared, the *Bacillus coli* score decreased; (3) hydrogen ion determinations on oysters spoiling in the shell showed little change in acidity; shucked oysters, however, became markedly acid during the first few days of spoilage; later, there was a reversal of reaction and the original pH was regained and maintained; (4) in the ice box the rise in acidity lagged two or three days behind and remained at a slightly lower level than at room temperature; at ice-box temperature the maximum total count was about one-tenth of the maximum count at room temperature; (5) the bacteria of the decomposing oyster may be divided into five principal groups—(*a*) the colon-aerogenes group; (*b*) the streptococci; (*c*) the 'water bacteria,' including members of the green fluorescent, the yellow pigmented, and the nonpigmented groups, and vibrios; (*d*) the anaerobes, and (*e*) the incidental organisms, such as the chromogenic cocci and the aerobic spore formers; (6) in shucked oysters the souring process may be initiated by either the colon-aerogenes group or the streptococci; if the streptococci are present in large numbers, the colon-aerogenes group is inhibited by the second day; (7) after a varying period of time, 12 days or longer, the water forms multiply rapidly, there is a reversion in reaction and actual decomposition of the oyster meat begins. Certain members of the green pigmented and the yellow pigmented groups produce changes in sterilized oysters comparable to those observed in the decomposition of market oysters, there is a slimy chromogenic growth and a marked softening, and, in some instances, liquefaction of the oyster meat when these organisms are grown upon them; members of these groups are always found abundantly in spoiling oysters, other water forms which are also abundant in the spoiling oyster do not initiate decomposition processes in sterilized oysters; (8) several types of anaerobes multiply in spoiling oysters and produce large amounts of gas, but apparently bring about no putrefactive changes.

Summary of the Purpose and Principles of Aeration of Water Supplies.—C. A. Emerson, jr. Proceedings of Eighth Texas Water Works Short School, Bulletin No. 1, January 23, 1926, pp. 78–83. (Abstract by W. H. Wendler.)

The aeration of ground water is usually for the purpose of the oxidation of iron, manganese, or organic matter and for removing volatile odors and gases such as carbon dioxide and hydrogen sulphide. These constitutents, when present to excess, impart color, turbidity, and sometimes taste to the water, and by deposit cause staining of plumbing fixtures and white clothing in the laundry. Carbon dioxide also dissolves iron from the interior of the mains. There have been instances in which samples of tap water showed six or more parts per million of iron in contrast to one part per million at the well.

Where iron is present it is readily changed by oxidation from the soluble ferrous form to the insoluble ferric hydrate, only one part of oxygen being required to oxidize seven parts of iron It has been found that if the dissolved oxygen content were permitted to rise above 50 per cent saturation, the iron and manganese could not be satisfactorily removed In some Massachusetts plants where manganese and organic matter interfered with precipitation of iron in fully aerated water, the tricklers were operated as submerged contact beds.

Aeration for removal of tastes and odors due to industrial waste pollution, particularly 'phenol' wastes from by-product coke ovens and wood distillation plants, has been of little practical value in most instances

Sometimes surface supplies, taken from the lower levels of large reservoirs or from rivers which have been ice blocked for long periods, are somewhat deficient in oxygen, and in these instances aeration was helpful

Connecting Safe and Unsafe Water Supplies.—Anon. *Public Works*, vol 57, No 8, September, 1926, pp 281–282 (Abstract by Dana E Kepner.)

At the conference this year of the State sanitary engineers a committee on cross-connections presented a report recommending the adoption by the conference of resolutions providing that "no physical connections should be permitted between any potable public water supplies, either through cross-connections, auxiliary intakes or by-passes, and other supplies except as follows: (1) With another potable public water supply; or (2) with a potable supply which is regularly examined as to its quality by those in charge of the potable public supply to which the connection is made." A cross-connection is defined as any physical connection whereby a potable public water-supply system is connected with another water-supply system, whether public or private, in such a manner that a flow of water into the potable supply is possible therefrom, directly through the manipulation of gate valves, because of ineffective check or back-pressure valves, or otherwise

The results from a questionnaire sent to the various State boards of health dealing with existing regulations in this respect are given.

Garbage Collection and Disposal.—Anon. *Public Works*, vol. 57, No. 10. November, 1926, pp. 385–387. (Abstract by C. L. Pool.)

This article is the first of a series in review of a symposium on garbage collection and disposal held by the sanitary engineering division of the American Society of Civil Engineers. Six papers constituting the article were as follows: A general review of the problem, by Samuel A. Greeley; a description of practice at Lansing,

Mich., by Edward D Rich; the same for the hog feeding for Los Angeles, Calif., by W. T Knowlton; a description of the Beccari system at Scarsdale, N. Y., by Arthur Boniface; one of high temperature incineration at Toronto, Canada, by A J. Burnett; and one of the Cobwell system of garbage reduction at Rochester, N. Y, by John V. Lewis.

Mr. Greeley discussed administrative and engineering problems encountered and outlined the procedure recommended to cities confronted with the problem. In connection with incineration specifications recently prepared by him the work was classified under five heads: (1) Incinerator furnaces and appurtenances; (2) incinerator building and scale; (3) chimney; (4) runway; and (5) sewers and sewage-disposal plant. A list of reduction plants in operation noted whether each was operated by the city or by a contractor. The Kansas City contract allows disposal by any satisfactory method. The contract price (1925) was $6.45 a ton for collection and $1 a ton for disposal.

Can collection practice at Lansing, Mich, is emphasized and constructional details of cans are given. Frequency and methods of collection are outlined and costs given include $0.91 per capita of the population served for collection in 1924.

Los Angeles practice is discussed, with quantities and costs noted. Material rejected by the pigs is covered with gypsum to conserve the ammonia content, dried, and ground for use as fertilizer.

Examination for Entrance into the Regular Corps of the United States Public Health Service

Examinations of candidates for entrance into the Regular Corps of the United States Public Health Service will be held at the following-named places on the dates specified:

Washington, D. C	February 7, 1927
Chicago, Ill	February 7, 1927
New Orleans, La	February 7, 1927
San Francisco, Calif	February 7, 1927

Candidates must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written, and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President, with the advice and consent of the Senate.

Requests for information or permission to take this examination should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

DEATHS DURING WEEK ENDED DECEMBER 18, 1926

Summary of information received by telegraph from industrial insurance companies for week ended December 18, 1926, and corresponding week of 1925. (From the Weekly Health Index, December 22, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Dec 18, 1926	Corresponding week, 1925
Policies in force	65, 797, 778	62, 410, 497
Number of death claims	12, 674	12 128
Death claims per 1,000 policies in force, annual rate	10 0	10 1

Deaths from all causes in certain large cities of the United States during the week ended December 18, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, December 22, 1926, issued by the Bureau of the Census, Department of Commerce)

[3] Data for 63 cities.
[4] Deaths for week ended Dec 17, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Norfolk, 38; Richmond, 32; and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended December 11, 1926, 39 States reported 2,143 cases of diphtheria. For the week ended December 12, 1925, the same States reported 1,679 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,360,000, reported 1,169 cases of diphtheria for the week ended December 11, 1926. Last year for the corresponding week they reported 911 cases. The estimated expectancy for these cities was 1,350 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-seven States reported 5,089 cases of measles for the week ended December 11, 1926, and 4,561 cases of this disease for the week ended December 12, 1925. One hundred cities reported 1,160 cases of measles for the week this year and 2,451 cases last year.

Poliomyelitis.—The health officers of 39 States reported 29 cases of poliomyelitis for the week ended December 11, 1926. The same States reported 41 cases for the week ended December 12, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-nine States—this year, 3,576 cases; last year, 3,203 cases; 100 cities—this year, 1,387 cases; last year, 1,280 cases; estimated expectancy, 1,062 cases.

Smallpox.—For the week ended December 11, 1926, 38 States reported 667 cases of smallpox Last year for the corresponding week they reported 365 cases One hundred cities reported smallpox for the week as follows: 1926, 65 cases, 1925, 119 cases; estimated expectancy, 69 cases No deaths from smallpox were reported by these cities for the week this year

Typhoid fever.—Three hundred and eighty-four cases of typhoid fever were reported for the week ended December 11, 1926, by 39 States For the corresponding week of 1925 the same States reported 444 cases of this disease Ninety-nine cities reported 61 cases of typhoid fever for the week this year and 111 cases for the corresponding week last year. The estimated expectancy for these cities was 87 cases.

Influenza and pneumonia —Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,600,000, as follows: 1926, 830 deaths; 1925, 799 deaths.

City reports for week ended December 11, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

The following table gives the rates per 100,000 population for 101 cities for the five-week period ended December 11, 1926, compared with those for a like period ended December 12, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 101 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 95 cities reporting deaths had more than 29,200,000 estimated population in 1925 and more than 29,730,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, November 7 to December 11, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

PLAGUE ON VESSEL

Steamship "Dacia"—At Haifa, Syria—On November 17, 1926, a case of plague was reported on the steamship *Dacia* at Haifa, Syria, occurring in a seaman. The vessel came from Rumania.

BERMUDA

Leprosy—Care and treatment of patients.—Reports of leprosy in the island of Bermuda, received under date of December 10, 1926, show for September, 1925, 8 lepers present, 3 male, 5 female, and for September, 1926, 9 lepers, 3 male and 6 female; one man and one woman, white, the remaining cases, colored. The isolation hospital not being equipped for the treatment of these cases, the lepers are cared for mainly by the parishes in which they reside and where they are segregated. The treatment includes administration of chaulmestrol.

CANADA

Communicable diseases—Week ended December 4, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended December 4, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Influenza	27							27
Smallpox				11	2	20	6	39
Typhoid fever	2	4	9	12	2	1	3	33

CHINA

Plague—Mongolia.—Information received under date of December 18, 1926, shows epidemic pneumonic plague present at Urga and Sanbese, Mongolia. Prophylactic measures were stated to have been put in force at Manchuria Station, on the South Manchuria Railway.

EGYPT

Plague—November 12–18, 1926.—During the week ended November 18, 1926, 1 case of plague, occurring in the district of Tantah, was reported in Egypt, making a total from January 1 to November 18, 1926, of 143 cases as compared with 137 cases reported for the corresponding period of 1925.

Alexandria—November 23, 1926.—On November 23, 1926, a case of bubonic plague was reported at Alexandria

Gharbieh.—From November 22 to 23, 1926, 2 cases of plague with 1 death were reported at Tanta, Province of Gharbieh.

FRENCH SUDAN

Yellow fever—Segou—November 23, 1926.—Under date of November 23, 1926, a fatal case of yellow fever was reported at Segou, French Sudan, West Africa.

GREECE

Plague—Patras—November 9–13, 1926.—Three cases of plague have been reported at Patras, Greece, occurring November 9, 11, and 13, respectively.

Typhus fever.—During the month of October, 1926, 7 cases of typhus fever with 1 death were reported in Greece.

MADAGASCAR

Plague—October 1 to 15, 1926.—During the two weeks ended October 15, 1926, 121 cases of plague with 111 deaths were reported in the island of Madagascar. The occurrence was distributed according to provinces as follows: Maevatanana, cases 17, deaths 17; Majunga, cases 6, deaths 2, Moramanga, cases 18, deaths, 18, Tamatave, cases 1, deaths 1; Tananarive (town), cases 16; deaths 14; other localities, cases 63, deaths 59.

Deaths among Europeans.—Of the 14 deaths from plague reported in the town of Tananarive 3 deaths were in Europeans, making a total of 5 deaths of Europeans from plague since August ,1926.

MEXICO

Malaria—Vicinity of Vera Cruz.—Information received from Vera Cruz under date of December 8, 1926, shows malaria present at Palmar, a small locality in the vicinity of Vera Cruz, with 2 fatalities reported to November 10, 1926. A physician of the State medical service has been in charge of the situation since that date. It was stated that at the outset he treated daily from 100 to 120 cases of malaria, with a few cases of dysentery. Population of Palmar, 350, including residents of near-by ranches.

SENEGAL

Further relative to plague—November 22, 1926.—Under date of November 23, 1926, 2 new cases of bubonic plague were reported in the interior of Senegal, West Africa. The cases occurred in natives and in the district of Diourbel.

Yellow fever.—Yellow fever was reported in Senegal, November 23, 1926, as follows: Four cases with 4 deaths, 1 case occurring in the

district of Kolda (Casamance) and 3 cases in the district of Sine Saloum. Of these cases, 3 were in Syrians and 1 in a European

UNION OF SOUTH AFRICA

Plague—Cape Province—October 31—November 6, 1926.—During the week ended November 6, 1926, a case of plague, occurring in a native on a farm in Colesberg district, was reported in the Cape Province, Union of South Africa

Smallpox—Natal—During the same period 7 additional cases of smallpox were reported at Durban, Natal, making a total of 49 cases with 9 deaths reported to date, occurring in Hindus or natives.
